3. Vigorous but shrubby growth, pink flower nearly globular capsule	3·70	0·14	trace	0·12	—
4. Under surface leaf purple flower, similar to Ledger but larger ...	2·88	—	trace	trace	—
5. Strong growing probably a hybridized Ledger...	2·41	—	trace	trace	—
6. Large leaf, vigorous, hybrid, pubescent ...	2·71	—	2·20	1·81	1·40

At the time the above analysis was received early in 1883, information on the subject of Ledgeriana was published in your columns, and guided by this and the analysis I resolved to cut out all trees except Ledgeriana of the purest type, this being done my original stock of 500 trees was reduced to 103; the trees are now five years and eight months old, and a few are bearing seed, while the balance have never as yet produced a flower bud, a good sign as to their purity of type.

At the end of last month I had bark taken from twenty-one trees, which are now bearing seed, and this has been analyzed in one lot by the Government Quinologist, Mr. David Hooper, whose certificate gives the satisfactory result of 11·31 sulph. of quinine, as an *average*. I believe this is the highest analysis on record, and it goes to prove that Wynaad is particularly well adapted to the growth of the most valuable variety of cinchona, *C. Ledgeriana*.—I am, yours faithfully, EDWARD HAMLIN.

P. S.—Mr. Lawson, the Director of the Government Cinchona Estates, who has inspected the "Chembaly" Ledgeriana trees, is about to propagate cuttings from them on account of the Madras Government. E. H.

PLANTERS' PLEASURES.

Sir,—I am not going to let your senior editor have it all his own way. The brag that he alone has been able to introduce a disease* into agricultural produce I mean to dispute. I have the honor to introduce to your notice another curse. I can't tell you its name, but I have a specimen to send to anyone curious to see it and who can identify. It affects cardamoms. I know of thirty-three per cent of a small clearing gone, ninety per cent of another of thirty acres, and fifty acres all gone in another place. Some say it is *drought*. But in the immediate neighbourhood of two of them are plants not affected. Others say the *wind*. Why should providence temper the wind to some only. Nice lookout for cultivators. When a plant dies from old age the whole thing goes together. When from drought there are the signs of want of moisture all through. When from wind the young leaves at the end suffer first. Now my introduction has none of these signs. I attacks old leaves first and eats them into shreds somewhat like a plantain's in a windy place, *beginning at bottom* and working up. Top leaf is the last to go. Then the stem breaks and falls. We used to think a coffee estate a fair fortune, but agents and *Hemileia vastatrix*† have cruelly disillusionized many of us. No doubt of a gold mine being in chocolate. Did n't ——— make four thousand off four acres! Liberian coffee was the next *ignis fatuus*, and was to do wonders: one bean to make a cupful of infusion! Nectar for Olympus. There is little growing, but production exceeds consumption. Cinchona was to pull us through everything. We have flooded the market. ——— of Hillside heaped his on drying ground and put firestick as the easiest method of disposal. It would not have paid charges to Colombo. Now here is cardamoms, which will grow anywhere. In how many cases does it pay? What between drought wind, unsuitable soil, thieves and disease it is not a lively lookout. Happy is the man with tea. We all believe in it at present.

The biggest and most generally indulged vices in Ceylon by certain classes in the community are lying and thieving. The former is only irritating to newcomers, charitable folks who believe all things. Thieving we all suffer from. However St. Nicholas's disciples have not lately had it all their own way. Formerly, if they half-murdered a watchman, broke into and robbed a store, they were generally let off, and

* Because we were the first to describe the gum leaf-disease of 1882, a correspondent actually gave our senior the credit of introducing it!—Ed.

† Which of the two panperized morons?

the watchman got all the blame. In the few cases which ended in conviction they had a grand friend in Chief Justice Phear, who would quash the whole, if committal had an undotted *i* or uncrossed *t*. We are fast becoming an Alsatia. Our present Chief Justice did his best to put it down, and will no doubt do some good. Not much, whilst jails are houses of gratuitous entertainment of high order for the dishonest. We 'll see the effect of new Code, singly opposed by the G. A. W. P. Watchmen however began to shirk work when exposed to murderous attacks and unable to defend themselves; so insist on being armed, and Mr. Saunders's pets are getting the worst of it, occasionally. A few more such, and thieving will require consideration whether the play is worth the candle. There is a story afloat for which I cannot vouch. A gang of eight thieves started to rob a cardamom plantation. Only six returned to their happy homes. The other two have been sought high and low, like the misletoe-bough bride. What has become of them? It is known the watchmen of the plantation had guns for shooting monkeys. The fact remains, thieves are fewer in that neighbourhood by a couple. [This, of course, is a goak.—Ed.] A SUFFERER.

MANURE FOR TEA, AND YIELD ON OLD LAND.

21st February 1885.

Dear Sir,—Can any of your readers give me some information as to the most suitable manure (other than cattle manure) for tea? Has artificial manure been applied to any extent?

It is obvious tea will have to be manured, some sooner, some later, the question of time being regulated principally by elevation. Tea, although a hardy plant with roots of great penetrating power, cannot be expected to continue giving crops of 400 to 800 lb. per acre, which means 14 to 28 cwt. of green leaf: if we include prunings the figures will be something like 28 to 56 cwt. per acre per annum. Low-lying estates, owing to the forcing climate they possess, will doubtless be the first to show signs of distress, and manuring ought therefore to be commenced in the third or fourth year; the fine soil generally prevalent in the upper parts of Dimbula, Dikoya and Maskeliya will probably continue giving good returns up to the eighth year, but it is also a question whether these returns might not be augmented, and the estates at the same time kept from falling off by periodical applications of manure, say from the fourth year.

The following comparison of yields may be of interest to those planting up old coffee land. A field of 20 acres, elevation 2,500 feet, abandoned perhaps ten years, was planted with tea in 1880. 10 acres of this field is fine dark free soil, and gave last year 250 lb. tea per acre, and the current year's estimate is put down at 450 lb. per acre. On the other half, which is poor stiff soil, the crop last season was only 130 lb. per acre, this year it will not be more than 200 lb. per acre, and it is questionable if ever that yield will be exceeded without manure.

With regard to this field one naturally asks: Will it pay to apply manure to land, which without it does not pay for upkeep? Would it not be preferable to abandon such tea and cultivate only selected portions of the estate which have been proved to yield remunerative crops and would therefore be reasonably expected to respond to liberal cultivation? S.

[With the qualification that the manure applied to tea ought to have a larger proportion of ammoniacal matter—say dissolved guano—we suppose what is good for coffee will be good for tea, say white castor-cake and either bone-dust or better still superphosphate of lime. There are few plants which so readily respond to manure in increased yield of better flavoured leaf. Colonel Money speaks highly of the effect of cow-dung, but says he has no doubt "highly concentrated chemical manures will be eventually much used on tea gardens." He mentions "Money & Ponder's chemical manure" as patented by Mr. Ponder and himself. All estate refuse should be utilized, and we should think that kainit as a source of potash would be useful. We trust those who have had practical experience will write on the subject. See Mr. John Hughes' remarks published on page 736. We are likely to hear again from this gentleman on the subject.—Ed.]

GOLD IN NORTH BORNEO.

27th February 1885.

Dear Sir,—The accompanying memo. and certificate of assay may be interesting to your readers.

The information contained in the memo. may be relied on, as it is compiled from materials placed at my disposal by the Secretary to the Board of Directors of the British North Borneo Company.—Yours truly,

W. D. GIBBON.

Memo. British North Borneo.

Kandy, 27th Feb. 1885.

The certificate of Assay signed by Messrs. Johnson, Matthey & Co. (copy of which accompanies this) confirms the existence of gold in the Segama, and since then a find has been reported in the Kinabatangan. There is thus every reason to think an alluvial deposit will be found to exist extensively over a very large area.

The black metalic sand which the Chief Commissioner of Lands, Mr. Walker, always found in conjunction with the gold dust, is an iron sand similar to what is found and smelted in New Zealand. For iron it is of no commercial value in Borneo at present, but it is interesting to know, that, if found in large quantities, it will be very valuable, for the specimens sent to England gave a result of 1¼ to 1½ oz. of gold to the ton.

The No. 1 specimen of gold washed in Sungei Bilang is of very good quality and estimated to be worth 72s per oz. The fifth specimen on the list marked A. rock is the sample which Mr. Davies brought from the Paitan Sugar reported in Governor Treacher's dispatch of the 30th October. This also contains gold to the extent of 3 dwt. to the ton.

The crystals sent home with the gold were so like diamond, that even the lapidary was deceived till he tested them and found them to be quartz.

Messrs. Johnson Matthey & Co. confirm Mr. Walker's opinion that better results will probably be obtained when the dry season will admit of working the old gravel deposits.

These gentlemen are sanguine about the mineral prospects of North Borneo territory and anticipate that valuable discoveries will be made as the country is developed.

The Directors of the Company trust that this report of the Assayists will lead to the Chinese taking up gold washing as they do in other parts of Borneo.

W. D. Gibbon.

Certificate of Assay.

The British North Borneo Company

Hatton Gardens, E.C., 5th Feb. 1885.

For British North Borneo Company.

We have examined the samples of mineral marked as under and find the following to be the result:—

No. 1.—Gold washed at Sungei Bilang, Segama River. Quality gold ·889; silver ·080.

No. 2.—Ore washed by Mr. Sachse for trial for tin. Produce of gold 1·500 oz. per ton of 20 cwt. of ore—no tin.

No. 3.—Ores S. Bilang, Segama. Produce of gold ·650 oz. per ton of 20 cwt. of ore—no tin.

No. 4.—Ore fused in a crucible portion of black dust from Sungei Bilang. Produce of gold 1·150 oz. per ton of 20 cwt. of ore.

A.—Rock. Produce of gold 0·150 oz. per ton of 20 cwt. of ore. (Signed) Johnson, Matthey & Co.

WARNINGS AND ENCOURAGEMENTS FOR TEA PLANTERS.

Upper Abbotsford, Lindula, 28th Feb. 1885.

Dear Sir,—In 1883 I dispatched to the London market a break of pekoe and broken pekoe in 1 lb. and 2 lb. packages and got respectively 2s 1d and 2s 4d to 2s 6d per lb. Encouraged by this successful precedent, I last year repeated the experiment, and, to my disgust, for tea which I valued at an average of 1s 4d I received an average of 1s 0½d (see last sales but one of Abbotsford tea). I would not have attempted to publicly explain the cause of this undeservedly low average, but for the following letter of explanation which I have received from Messrs. J. M. Robertson & Co., and which, I think, ought to be published to prevent others falling into the same mistake. It seems to indicate that buyers in England do not desire Ceylon tea in order that they may sell it pure, but that they may mix it.

(*Copy.*) Colombo, 21st Feb. 1885.

A. M. Ferguson, Esq., Abbotsford.

Dear Sir,—We annex for your guidance an extract from a letter received today from Messrs. Baring Brothers & Co., which, we think, has special reference to Abbotsford tea.—Yours faithfully,

J. M. Robertson & Co.

(*Extract referred to.*)

"Please take note that in consequence of the tea you send us being in such small packages it is almost unmarketable; and with regard to the last parcel we sold it was with much difficulty that our broker could hold the buyer to his bargain."

Now for the encouragements. In giving the Abbotsford statistics, I know I am thought by many to be blowing my own trumpet, but I think it will be admitted, if the gum-disease of 1882 is called to mind, that I am as ready to give the dark side as the bright. I am thankful to say that it is very bright just now, while Ceylon is in sad need of all the cheerful news that can be given at present. Our tea is simply *glitteringly* green with health, and here are my returns of made tea to end of this and last week:—

Cattle-shed Field, 15 acres 3,133 lb.; average for year if same rate could be kept up, 1,206 lb. per acre.

Bungalow Field, 5 acres, 881 lb.; average as above, 1,017 lb. per acre.

Roads and Drains, 20 acres, 2,846 lb.; average, 924 lb per acre.

Large Field, 70 acres, 8,947 lb.; average, 738 lb. per acre:—this week's picking will raise this latter considerably.

My young plants that I am picking from cannot possibly consist of more than 10 acres 3 years old and 70 acres 2 years old, chiefly scattered among coffee and cinchona; yet they have given me in nine weeks of this year 3,058 lb. made tea, or 220 lb. per acre.

My pluckers to the end of last week have averaged 21·8 lb. green leaf each (3,065 pluckers have gathered 65,840 lb. green leaf).

I know that other estates are doing equally well, but they hide their light under a—Sirocco!—Yours truly,

A. M. Ferguson, Jr.

Demerara.—The weather and the crops in the wet season has now fairly set in and copious rain has fallen throughout the colony, though the downpour has neither been so heavy and continuous as the planters hope it will prove to be. "In Essequebo," writes our correspondent, "I hear some of the estates have not yet had sufficient rain to clear the draining trenches of lees, and the smell alongside the public road is very offensive. Berbice and Demerara seem to have been favoured with more rain than the other county. The effect of the late drought on the spring of the canes cut lately has been very serious, and I hear of estates abandoning large stretches of cultivation from the want of plants to supply the blanks in the fields. As many of the March canes have already been cut owing to premature ripeness, very little sugar will be made during the first three months of this year, and the abandonment of considerable acres of cultivation will curtail the crop for the end of the year, so I think it not unlikely that the crop of 1885 will not exceed 100,000 hhds."—*Royal Gazette*, Jan. 3.

Profits of Oranges.—A correspondent from Florida writes, that "orange culture is one of the most profitable enterprises any one coming to that State can engage in, especially if one can manage to sell out his orchard."—*Gardeners' Monthly.*

Returns from Coconut Planting.—An old coconut planter writes:—"Mr. Rama Nathan's estimate of the profits is R30 per acre, which is pretty near the mark for the average native property. The cost of getting up a property is very slight. The original cost of the land say R15, some part of which is recovered by the land share of the goyiya crops; then there is the felling of the jungle twice between the goyiya's work and coming into bearing about the tenth year. On the whole I should say, that, on the most common system, the proprietor of a coconut garden seldom expends more than R40 to R50 an acre during the non productive stage. Of course those who have faith and means can spend very much more with advantage in earlier and heavier crops. I have already expressed my belief that it is a profitable investment of capital to bring up the bearing to 100 nuts per tree annually, but this is too European for a common practice among coconut proprietors."

Sugar Cultivation in Java.—Several Batavia mercantile firms have memorialized the Governor General in favour of the remission of taxation on sugar in Java and Holland, and lowering freight charges upon that article on State railways, the result being that they were officially notified in reply that their application will be taken into consideration. Meanwhile, cane growing in Java is threatened who ruin by a foe far more dangerous than low prices or beet-root competition, by the appearance and steady spreading for years in the province of Cheribon of a disease called *Serch* among growing canes, whereby the stalks shrivel up until they become useless for crushing purposes. Neither is the origin of the disease nor any remedy for it known, the only thing certain being that it gains ground year after year, slowly but surely.—*Straits Times.* [It seems as if every product largely cultivated—wheat, potatoes, vines, coffee and now sugar—will, sooner or later, be attacked by some destructive pest.—Ed.]

Coffee and Labor in Brazil.—Mr. Van Delden Laerne,—who in consequence of the alarm among Java planters arising out of the fall in the price of coffee brought on by the over-production of that article in Brazil, was recently commissioned by the Dutch Government to proceed thither and report on the condition and prospects of coffee growing there—has embodied his experiences and conclusions in a recently published report filling a volume containing 600 pages. In his opinion there need be no fear of any increase of the Brazilian coffee export, owing to scarcity of labour in Brazil, which is so great that, whenever the crops are heavy, the growers are so short-handed that delivery falls short of requirements, so that the exports do not keep pace with the outturn of the crops. Professor Couty, a Brazilian, whose report on the same subject is noticed in the Sourabaya *Courant* of the 15th January, ascribes this scarcity of labour to the supply falling short by slaves dying out in great numbers yearly, and by free people declining to work on the estates. Chinese labour being too costly and European labour unavailable, Brazilian coffee growing is in a very depressed condition.—*Straits Times.*

The "Dadap" (Malay no doubt) is the name used in Java for an *Erythrina* which is, in that island, the favourite shade tree. Similarly an *Erythrina* is used as a shade tree for cacao in Trinidad and other West India islands and in South America, where the tree is called the "mother" (madre) of the cacao. *Erythrina Indica* is very common in Ceylon and is now conspicuous in Colombo* and along the line of railway, from its blaze of scarlet blossoms. It is called by some "the Indian coral-tree." Travelling with Dr. Trimen a few days ago, we attracted his attention to a bright group of trees on the side of a hillock near Polgahawela, and he said: "That must be indigenous." This tree is one of the few in Ceylon (the "cotton" trees for instance, which are deciduous. A fresh flush of leaves succeeds the scarlet blossoms. The crows are constantly at work amongst the red blossoms, but whether they eat the petals, suck nectar from the heart of the flowers, or feed on insects which are attracted by the blossoms, we cannot say with certainty, although we think the birds eat the flowers. *E. Indica* is a common hedge-plant in Ceylon, growing readily from cuttings. The timber does not seem to be of great value. Gamble in his "Manual of the Timber Trees of India" enumerates seven species of Indian *Erythrinas*, "soft-wooded, handsome flowered, deciduous trees." He notices *E. ovalifolia* as a tree of the coast forests of Burma and the neighbouring region of Assam &c. *E. lithosperma* and *E. holosericea* are also natives of Burma, while *E. resupinata*, a herbaceous plant, grows amongst the grass of the Himalayan terai. Gamble describes *E. suberosa* as growing up to 3,000 feet. The soft, light wood is used for scabbards, sieve frames, and occasionally for planking. *E. Indica*, (the most common in Ceylon) is "the Indian coral-tree," the *dadap* of the Malays and the *erabadu* of the Sinhalese. Its structure is much the same as that of *E. suberosa*, but the young stems and branchlets are armed with prickles. It is cultivated throughout India and Burma and is wild in Oudh, Bengal, South India (Ceylon?) and Burma. The weight of a cubic foot of the wood is about 18 inches. Gamble gives a better account of the timber than we anticipated, and perhaps it might be utilized for tea boxes. We quote as follows:—"Wood rather durable; though it is so light and open grained, it does not warp or split and it varnishes well. It is used for light boxes, toys, scabbards, trays, and is often grown as a support for and to give shade to the betel pepper vine." Then comes a notice of *E. arborescens* which grows up to 7,000 feet on the Himalayas, and there are avenues of it at Darjiling. The *dadap*, which is probably *E. Indica*, or closely allied to it, seems to have been valued as a shade tree from its deciduous habit, the impression being that the leaves are shed when light and air are most required by the coffee and cacao. But when we were in Java in 1881 the favourite shade trees were *Albizzia Moluccana* (timber brittle and of little value) and the beautiful and valuable "toon" tree, the red cedar of India. This latter seems to us the tree which ought to be grown on estates at high elevations: this and *Grevillea robusta*. From the translation of Mr. Scheffer's Report on the Buitenzorg Botanic Gardens, which we published in the *Observer* in 1880 and reprinted in our Handbook for 1880-1, we quote as follows:—

The demand for seed of *Albizzia moluccana* was very great. Of this tree Mr. Scheffer says:—"The culture of *Albizzia moluccana* is very easy. It is sown in hothouses or nurseries. The seeds are soaked in water before sowing. It is well-known that most of the coffee planters in Java employ fullgrown forest trees as shade for coffee. In some situations this proceeding appears to me unnecesary, in others it is destructive; but the plantations are situated in circumstances so varied as regard climate and distribution of rain in the different months that it would be very impudent to lay down a general rule. For shade the dadap (*Erythrina* [spec. div.) is generally employed. Although this tree is preferable to those which are used in Ceylon (where *e. g.* the *Artocarpus integrifolia* is much employed) it has many drawbacks. In the first place the dadap, which is always propagated by cuttings, soon rots at the lower extremity of the trunk; then it suffers much from the larvæ of a *carembyx*. which eat the pith and cause the death of the tree; besides, the leaves are largish and end in elongated points which form as it were watercourses, by which the rain always falls in the same spot on the coffee trees; finally, the dadap has too bushy a foliage and does not attain to any considerable height. The *Albizzia* on the other hand grows more quickly; it gives a shade which is placed at a considerable height above the coffee trees, which allows a free current of air; its foliage is not too thick. and the leaves are divided into numerous folioles of small dimension. Further, the folioles, as is always the case with mimosas, are pendant and turned downwards during the night, so that the dew and the moon's rays can penetrato to the plantation. For reforesting, if only an amelioration of climate is in view, or firewood is required, I know of no tree better than the *Albizzia*. Mr. Dennison planted it in order to obtain firewood for his limekilns, and he writes to me that he has no culture more profitable. Trees of three years old were large enough to furnish planks of sufficient dimensions for a box containing 70 kilos of tea." The director received very varying reports as to the benefit of this tree, some saying that it gave very little humus and no shade, while others report the exact opposite. There is no question however that the tree is very fragile, but Mr. Scheffer states that this fault may be remedied by thoroughly pruning the tree when young. A Mr. Wiusser reports that the plant is slender, that the shade is too dense, that the branches are too horizontal and too low, and that consequently the tree hinders evaporation and thus gives rise to many evils in the coffee. Mr. Scheffer answers these complaints by saying that if it (the plant) is slender, the other statements cannot be true, and if the latter statements *are* true the complainant has not followed the directions given as to pruning. A Mr. de Haan cut down some trees for firewood, and he obtained excellent charcoal for his tea-house.

It will be seen from the above that Mr. Scheffer's opinion of the *dadap* as a shade tree is not very favorable.

Russian Duty on Tea.—Notwithstanding the protest of Mr. Katkoff, the Russian Government has raised the duty on tea by 400 copeks per pood, which is between 4*d* and 5*d* per lb It is noteworthy that this is levied solely on tea across the European frontier, so that the increase operates as a differential duty on tea coming overland *via* Russian Turkestan. The net result, however, will be the same—namely, that the moujik, who drinks more tea than any other man in Europe, will have to pay about 6*d* a lb. more for all the tea that he consumes, while the wealthy classes who drink only the overland tea, will find the price of their favourite beverage remain unchanged.—*European Mail.*

An Enemy of Tea.—A Dikoya planter writes:—"I send a match-box containing tea leaves affected by some insect which curls up the leaf and causes it to die: the green leaves are in first stage and contain small white caterpillars; the dry ones are in later stage, when insect appears to have left. There a is lot of it here, and in nearly every case it attacks the third leaf of the young shoot. I shall feel much obliged if you can tell me what it is, and whether likely to prove a lasting pest; also, if the big leaf at bottom of bough shows any traces of red spider." Our entomological referee writes:—"All I can say about it is, that the mischief is done by a leaf-rolling caterpillar, which probably turns into a small inconspicuous moth. I have examined the huge tea leaf, and can find no traces of red spider upon it."

* There are fine specimens in the grounds of "Temple Trees."

BONE MEAL MANURE.

TO THE EDITOR OF THE "FIELD."

Sir,—Your correspondent T. P. T. asks me to inform him where pure bones, such as I described last week, can be obtained, and I now myself offer to sell to him from one ton up to one hundred tons of pure bone meal, guaranteed 52 to 57 units of phosphate of lime, and 4 to 5 units of ammonia, at the prices I quoted, namely £6. 10s. per ton, to be analysed either by Voelcker or Sibson at his option; and I leave this offer open to him for one week, to give T. P. T. time to make arrangements for concluding what he describes as a "most desirable investment." I, of course, do not expect T. P. T. to be a buyer of bones, and I should not have answered him in this strain except that, throughout the whole of his letter, he throws a doubt upon the accuracy of my statements; and I think the foregoing challenge will close a correspondence which could only be of an argumentative character.

The valuations T. P. T. gives are very amusing, and he will no doubt have had pointed out to him before this that he is confounding the phosphate of lime in bones with soluble phosphates—that is, phosphates soluble in water (superphosphates), and which have been made so by the aid of either sulphuric acid or citrate of ammonia. There are of course no soluble phosphates in bone meal.

Again, T. P. T. states that the lowest price at which he ever heard of phosphate being sold was "a large order at Liverpool," where soluble phosphate was sold at 2s. 6d. per unit. In this remark also T. P. T. is much behind the times. For many months past, and up to the present moment, soluble phosphates have been selling in retail at Liverpool for 2s. per unit, as the manufacturers there know to their sorrow.

There never was a time when manures could be bought so cheaply as at present; and landowners and farmers can improve their land and increase their crops now much to their own advantage—the only thing necessary on their part being a fixed determination to buy only such manures as will be sold upon a guaranteed analysis. The question will be asked, "When chemists themselves differ, who will sell manures on a guaranteed analysis?"

This apparent difficulty would at once be overcome if buyers and sellers would agree upon and adopt a margin. Analytical chemists do differ, as all experienced men admit, but only to a reasonable extent; and any respectable importer or manufacturer of manures, who has confidence in the genuineness of his own goods would sell upon an analysis within a margin. A reasonable margin on ordinary manures would be 1 per cent in the ammonia and 5 per cent in the phosphates. For example, an importer receiving a cargo of 500 tons guano, which on landing analysed 8 per cent ammonia and 50 per cent phosphates, would run little risk in guaranteeing to the retail buyer an analysis within the margin previously named, that is to say, from 7 to 8 per cent ammonia and from 45 to 50 per cent phosphates. Between 30,000 and 40,000 tons of manures pass through my hands every year, and my experience tells me that only by an established and uniformly recognised margin can the present confusion and mistrust be satisfactorily arranged. —Bones.

KALUTARA DISTRICT.

LIBERIAN COFFEE, COCOA AND TEA.

I recently paid a visit to one of the first opened estates in the Kalutara district. As a matter of course it, as well as all the estates opened immediately after, was planted with that gigantic swindle, Liberian Coffee. Soil was supposed to be of little consequence, as long as the elevation did not go beyond 2,000 ft. Thus we find that the stiff, damp, ferruginous laterite of the Kalutara district, which a moderately experienced planter in a calm moment would have condemned as a coffee soil, was thought good for Liberian coffee as long as the maximum elevation was not over-stepped. Strange to say, even Cacao, a plant that the late Dr. Thwaites informed planters, in a circular issued at the instance of Government, required a deep, rich, loamy soil for its successful growth, was also planted. I need not detail the sequel. Suffice it to say that Kalutara is at the present moment a Tea district. The generality of the soil is not what one would call rich in the general acceptation of the term. But being moist, and ferruginous, it makes what is called a good Tea soil. For rocks, commend me to the Kalutara situated. If the rocky hills had been situate in the vicinity of the capital, the owners thereof would have netted a considerable sum, by supplying the breakwater with stone. The first introduction to the district is through a clearing which on a moderate computation contains three-fourths rock. Stone, stone we see on every side. Every estate seems to have its "Rocky field" of larger or smaller size; but, strange to say, the usual accompaniment of rocks—a rich and free organic soil—is not met with here. A thin layer of mould overlies the rocks, which when displaced by the first rain-storm, reveals the usual laterite formation. Tea grows luxuriantly here, and on the estate I visited, the rolling hillocks of the same lay as Mariawatte, which forms the better part of the estate, grows as fine Tea as can be seen anywhere. Tea seems to be as fond of moisture as the coconut tree, if one is to judge by the truly magnificent growth in the drained swamps, where the bushes were in advance of the Tea planted the previous year on the hillsides. Moisture must be ever present at the roots, and yet the bushes seemed to revel in it, while Coffee under similar conditions would have succumbed to "wet feet." The estate I write of has been most carefully and intelligently opened. It is well roaded and drained, and amongst the rocks, where systematic draining is impossible, the ground has been terraced with the rocks, on a level trace, with drains cut wherever practicable to carry off the water of storms. Wash has been minimized, and a neat and finished appearance given to the place. I have seen a few good estates, in my wanderings, but a cleaner estate than this I never saw. I walked over the better part of its 250 acres, and all the weeds I saw would have not filled half a cooty sack, and these were met with on the damp sides of ravines in the form of grasses.

The great want of the district is a cart road. A tolerably fine cart road runs as far as Tebuwana and ends with a wide bridge over the river. Beyond is a bridle path, a sop granted by Government to stop the outcry raised by the planters for a cart-road. Till Arapolakanda, the first estate, is reached, the road runs, except in two instances where embankments have been thrown over lowlying land, through flat meadow land. The only cost incurred here is in cutting drains without outlets, and thus limiting the width of the road-way. From Arapolakanda and beyond, the road runs through estates. Almost one of the first sights that meets the eye of the traveller on entering this planting district, is a clearing of rubber, planted about eight feet apart and leafless. The trees if not dead, are next door to it. This, the result of about a twelve months' neglect. The jungle growth under is only a few feet high, sparse, and cannot in any sense be said to have choked the rubber trees, which are over twelve feet high. Taking science as our teacher, one would be inclined to argue that the shading of the soil by this undergrowth, would, by preventing its caking under tropical sun, and being washed by tropical rains, be of benefit to the larger growth. In practice we find that such a tree must be cultivated the same as other products.—"Examiner."

PRUNING.

In continuation of our remarks upon the rationale of Pruning, it may be repeated that its successful management depends upon the nature and mode of growth of the plant, varying in each case, and upon the object proposed to be obtained. Suppose, for instance, timber to be the object in view, theory and practice alike concur that as a general rule, subject to exception in particular cases, no more pruning should be done than can reasonably be avoided. Cut away the diseased parts, and those which are disproportionate or misplaced, secure the proper balance of growth, and ensure its right direction, and leave the rest to Nature, remembering that if meddlesome pruning be bad, negligent pruning may be worse. When Nature prunes she does it, not by the removal of large limbs, but by the removal of a large number of small twigs, which die or lose vigour by being over-shaded, as in the case of so many Thuias, and even in Oaks and Poplars. The recommendation, then, to

plant thick and to thin early is a sound one to follow as a general rule, unless in some easily understood and exceptional cases.

In pruning for fruit the case is quite different, and greatly depends on the nature of the tree, whether it produce fruit-spurs or not, whether it bear on the old or on the young wood. The main object is, first of all, to get a tree, to secure a framework and a sufficient supply of reserve matter in the bark or young wood to ensure the formation of fruit-spurs or to concentrate the reserve matter in particular parts of the tree where it is most likely to be useful.

The object here is first to secure a due amount of vegetative growth, and, this done, to direct the energies of the tree, as far as may be, to the production of fruit-spurs. To this end any excessive or unnecessary wood may safely be cut away, as well as any that may interfere with the form wished to be given to the tree to adapt it to its growth as a pyramid or against a wall. The numerous methods of effecting this are known and generally practised. The result of these procedures is seen in the uniform proportion and balance of the vegetative and of the reproductive organs, which skilful pruners, especially those of the old school, were so successful in obtaining.

In the case of pruning for flowers—as, for instance, in Roses—the object is to secure perfection in the flower. Here perhaps more than in any other case the horror of the theorist is excited; here perhaps the procedures of the pruner are most radical. Here, therefore, is it more particularly desirable to remember that the object is not timber—not even fruit or seed—but simply brilliant flower. There is comparatively less necessity for the accumulation of reserve stores, as the flowers form rapidly on the wood of the year, quickly assimilate the food they obtain, and utilise it at once. The cutting away of the old reserve organs is, therefore, of the less consequence, and, moreover, even where the hardest pruning is practised there is the reserve in the stock still available, and the roots are ready to come to the aid of the newly-formed leaves at once. Then again hard pruning for Roses finds a justification in the fact that the Rose is "spring tender," starts early into growth, and thus is liable to have its shoots killed by frost. The delay occasioned by hard pruning obviates this loss. Nevertheless, Roses do die, and no doubt they would not die so soon were the extension system more generally practised, but the results to the Rose lover would assuredly not be so satisfactory. In the case of the Vine the general principles are the same as in the Rose, but the Vine is less often grafted, and contains in the old rods a large relative amount of reserve nutriment. Here again the gardener has to consider whether it will pay him best to have a perpetuity of small bunches or a number of larger ones of better quality for a shorter period—whether the extension system will suit his requirements better than the rod and spur system usually adopted. No doubt if the production of matured seed and robust seedlings were the object, the extension system would practically and theoretically be the best in the long run, but for general purposes we require the fruit and not the seed—the requirements, as was stated in a previous article, being different in the two cases, at least in degree.

The same general principles apply in the case of root pruning, a procedure utterly at variance with the benefit of the individual plant; but which, when judiciously managed, is of great benefit to the cultivator, and of no appreciable harm (under the circumstances) to the plant.

With pruning is necessarily associated training, the objects of which are identical, and which ensures an equal amount of leaf action by a smaller number of leaves, because each leaf and each bud is, by skilful pruning and training, so placed as to get the most advantage from the light and heat. Each leaf here is placed under the most favourable circumstances possible, and has not to fear the injurious competition of its fellows. In fact, each leaf is in a degree placed under the same favourable conditions that a plant in a pot in a greenhouse is, as compared with one planted out, and having to take its chance among a host of competitors. In spite, therefore, of the now wholly untenable explanations afforded by the gardener and forester, and to which we alluded in a previous article, their practice is abundantly justified both by results and by modern theory when the objects of the operation are duly considered, and the mode of growth and habit of life of the plants duly weighed.—*Gardeners' Chronicle.*

THE MACKAY (NORTHERN QUEENSLAND) PLANTERS' AND FARMERS' ASSOCIATION

have completed their arrangements for indenting European labourers under the conditions suggested by the present Government. The trial shipment will number about 600, and it is intended, if possible, that these shall be Swedes, Norwegians, or Danes. In order that these immigrants may fully understand the work they will have to do, the rate of wages prevalent in Queensland, the feeling of the labouring classes to their introduction, and the inducements there are in the colony for the immigrant to seek it as his home, the Mackay association have published a pamphlet, setting forth fully and plainly all these particulars, and a copy of this will be given (translated into his own language) to every immigrant before signing his agreement, so that there can be no possibility of any after-statement that he was brought out under false pretences and with ut full knowledge of what he was going to do. The separation movement is rapidly gaining strength. The southern opponents would pass it off as entirely a planters' idea, so as to get coolie labour. I am in a good position to know that this is not the case. The planters may have had something to do in initiating the idea, by their constant assertions that separation was the only remedy against political oppression; but as far as organising or even starting the present movement they had nothing to do with it. Their sympathies are, of course, entirely with it, and by funds, and in every way possible, they will back it up, but the movement is entirely under the control and in the hands of the townspeople. Not one of the leaders of the movement but are in favour of federation of the colonies, but climatic or geographical separation must precede federation. The colonies must be divided to a greater extent than they are now before unity will be possible in one general council. In other words, complete local government in land, law, and taxes, must be given to each district, then one representative of Royalty and one capital town would be sufficient for the whole of the Australians, and one general council could decide upon national and foreign matters. That is the planters' view of the movement, whether it results in coloured labour for them or not.

It is my pleasing duty to have to write of as grandly favourable weather as the sugar planter could possibly desire. Your southern farmers of non-tropical Victoria can simply form no idea of the rank and amazingly rapid growth of weeds in this climate during the wet season, and cane is not able to hold its own in its struggle for existence with these robber plants, unless man comes to its aid until the leaf growth is so dense as to smother everything below it. Here is where the black—and cheap—labour comes in, for a multitude of hands and feet, each pair animated with individual intelligence, although not necessarily endowed with much strength, are required so as to get over the fields quickly, or the cane suffers correspondingly. Upon the extensive, stony scrub soil hills which are so fertile, no machine labour can ever be employed—the hand-hoe and the pick will ever be supreme; but on the open fields machinery and horse labour can be used to assist the hand labourer; but until machines are invented which have some intelligence—a very small amount would do—the planter will have to depend upon cheap, and that means coloured, humanity. However, to those planters who have abundant labour at command, very heavy crops are certain to be harvested next year, and this remark applies not only to this Mackay neighbourhood, but to the whole of the sugar-growing centres of Queensland.

The planters have had another snub from our statesman-like Premier over the matter of cheap European immigration, although they score one against him in exposing the hollowness and insincerity of his statements. You may perhaps remember that in one of my previous letters I mentioned that where the coloured labour question was before the House, Mr. Griffith, when he set his foot down against coolies, said that the Government were quite willing to introduce emigrants from Europe, who could be got for 10s. per week, and an act was passed to this effect, the planter having to pay £2 towards the passage and to hunt out and

engage his men. The Mackay planters consequently set earnestly to work to carry out this experiment of the Premier's, and so issued a pamphlet, which stated plainly and fairly the nature of the agreement; the term was for two years at a wage of £20 per year, plus rations and passage free, the work that would be required of the immigrant, and the inducements for a man to come to the colony and work for a short time below current rates. A copy of this pamphlet, translated as required, was to be given to every labourer before signing his engagement, so that there could be no possible excuse for him to say he did not know all about the matter after his arrival. Nothing could have been fairer than this course taken by the Mackay Planters' Association, and they entered for 1,000 labourers. There was a five hours' debate in the House over this now celebrated pamphlet, and the result is that the elasticity of our chief statesman's promises is such that he now repudiates the idea of cheap European immigrants, declines to introduce them upon what he calls the planters' terms, when in reality they are his own, and the whole sentence falls to the ground. Although the planters were never sanguine as to the success of these cheap whites, yet as they did their best to fall in with the Premier's views, he might have saved them the insult he has bestowed upon their good intentions. It is in such ways as this, that as in irritating annoyances, that the present Government is fast helping on the separation movement, and any far-seeing man can see that the epitaph written upon the grave of Samuel Griffith will be, "The Man who Lost North Queensland."—*Australasian.*

THE MANGO: ITS PROPAGATION AND IMPROVEMENT.

Europeans have never thought of keeping and sowing the infinity of Mango-stones of the best kinds, but have invariably thrown them away as worthless. One might ask how did all these fine kinds of Mango come into existence? There is, in my opinion, no other way of explaining the phenomenon than by referring them all back through many ages to the wild kind, the Mangifera indica of botanists. Natives of course account for them much more simply, viz., by God's will.

The jungle Mango, bad as it is, is eaten by natives. They throw the seeds about, and in the rains a large number of them germinate. The native has a very tender feeling for any plant that bears fruit, however bad. In weeding he never attempts to uproot a Mango seedling, or any other fruit seedling, even if he found it in the midst of your choicest flower-beds. This feeling, and the ease with which the Mango-seed germinates in the rains; the turpentiny taste of the leaves; there being in the rains a lot of sweet herbage for the cattle to feed on, so that they would neglect the Mango seedlings; all give this tree a great advantage in its struggle for existence; so that man has been unconsciously sowing Mango seeds since the beginning of time, and thus new varieties in course of generations were created. As new and better varieties came to his notice he of course preferred them to the jungle kind, and went on for ages unconsciously selecting and sowing new kinds, until he learnt, by means of grafting, to propagate the very kind that most took his fancy, and so he multiplied the good kinds. When he wanted timber for his dwellings he naturally cut down the trees that he liked least—that is, those which produced inferior fruit; and so continued selecting, propagating, and reproducing by seed, until our present day, when we find hundreds of charming varieties of one of the finest fruits in the world. The native name of the Mango is Am, which means provisions. This name shows that from time immemorial the fruit of the Mango has been used by natives as food. Even now, when Mangos are plentiful and cheap, natives almost live on them. For a native to eat fifty at a sitting is no uncommon thing.

Some time before I left Lucknow I had commenced sowing seeds of good kinds of Mangoes with the view of raising new varieties; and Mr. Ridley, in his Report for 1879-80, stated that of four seedlings which I had planted, and had been fruiting, one, which I had called *Runtra*, turned out good and well-flavoured, the other three were not worth keeping. Well, one in four is twenty-five per cent, and that is a very fair percentage for seedling fruit trees to turn out worth keeping. Some horticulturists would probably be satisfied with one in a thousand if that one turned out a treasure.

No real progress, however, can be expected in the creation of new and improved kinds without systematically planting seedlings of good kinds by thousands in orchards, or what natives call *baghs*. Then there would be a chance of a number of new and possibly startling varieties turning up. Attempting to produce new varieties by sowing seed on a small scale is likely to prove disappointing. The Mango seedling takes about seven or eight years to flower, so that, say within ten years, the result would be known. The Mango tree, although it may not produce first-class fruit, is by no means valueless; the fruit, even of the commonest kinds, is saleable, and often, though stringy, is very palatable. When of a certain age the tree can be sold for timber, which is universally used by natives for all purposes.

A correspondent of the *Bombay Gazette* states that Mango trees over 18 feet in circumference are not uncommon. Considering that the numerous splendid varieties we have could have originated from no other than the wild Mango, there is no good reason for supposing that, starting from the seeds of the present good kinds, provided they are planted in sufficient numbers, still better varieties would be created. It should not, however, be hastily concluded that grand results can be obtained in a few years. It should be remembered that the present kinds, for all we know, may have taken hundreds, nay, thousands of generations, to bring to their present state of perfection, although probably it was all done by a natural and unconscious selection through the fondness of the natives for this tree, and probably also through its inherent fitness for the struggle of life. If planting good seed, and selection of the best for propagation, be done systematically and scientifically, there is no reason to believe that even one generation might not witness a vast number of additional superb varieties.

Judging from the multiplicity of aromas of which this fruit is capable, it may probably have a great future before it. The great want is late and early kinds. The Mango generally comes with a rush, and lasts for only a couple of months. Of very early kinds I think there are few; of late kinds I know only one called *Bhadanya*, which ripens its fruit towards the end of September.

Young Mango trees are liable to be killed or badly injured by forst. On the morning of January 8, 1874, when the temperature on the grass in Lucknow was 5° Fahr. below freezing-point, and when fifty Mango trees of the youngest were killed outright, and 325 more or less injured, this very *Bhadanya* stood the frost very much better than all the other kinds; so that it is evident there is much room for new kinds, especially hardy, late, and early varieties. In my experiments I found that grafts taken from old trees thrived badly, and many of them died, while of those taken from young trees very few died. For two or three years after the graft is separated from its parent, it requires especial nursing.

I know of only two animals which are injurious to the Mango tree; one is the larva probably of some kind of beetle, which natives call *Macrora*. It burrows between the bark and the wood, and if not dug out will eventually kill the tree. The other is an underground rat. In its mining operations if it should come across the main root of a young Mango tree it does not hesitate to gnaw its way through it, and thus kill the tree.—E. Bonavia, M.D., Etawah.—*Gardeners' Chronicle.*

THE CULTIVATION OF SUGAR BEET IN ENGLAND.

We call the particular attention of our readers to the subjoined report by Professor Church as to the growth of sugar beet in 1884, and especially to the fact that previous investigations carried out by him at Cirencester appear to indicate that the percentage of sugar is not entirely a question of summer heat, although there can be no doubt that it is one of the main factors. But what we would specially point out is that, by careful attention to instructions issued by the proprietors of the sugar factory at Lavenham, a crop may be grown in ordinary

seasons, which contains the necessary proportion of sugar for profitable extraction, and which is of sufficient yield per acre to repay the farmer for his trouble and cost in growing. Moreover, if for any reason the supply exceeds the demand, and the crop cannot be sold to the factory, it will prove of great value as a cattle food, quite equal to a much heavier weight of mangolds, inasmuch as it contains less water, and the sugar is very feeding.

The farmers in the districts adjoining or within practicable reach of Lavenham may well pay attention to this renewed demand for sugar beet, which can be grown on a considerable variety of land, strong or light, provided the surface is well worked clean, and the proper kind of seed is sown in the manner recommended, and ordinary attention paid to cultivation. Crops ranging from twelve to twenty tons per acre may be looked for, and such will pay much better than wheat at present and probable rates. If the experiment proves a success at Lavenham, it will be followed elsewhere; and over a large area of the midland and southern counties the soil and climate are suitable for the extended growth of sugar beet.

To Messrs. Bolton and Partners, Limited, 4, The Sanctuary, Westminster, S. W.

Gentlemen.—In accordance with your instructions I have visited and carefully inspected the chief districts where sugar beets have been grown this year for your new sugar factory at Lavenham. * * * * *

Golden Rule for Growers.—In the majority of the past season's trials, sufficient attention was not paid to the golden rule of having as close a plant as possible. Small roots and many of them are best, both for the grower and the sugar maker. The smaller the root, the richer it is in sugar; the less saline matter does it extract from the land, or the manure; and the easier it is to lift. When the roots are near to one another the bulbs are not so much expressed, and the proportion of leaf to root is smaller; they are also less likely to be fanged and forked.

Advantages of a Close Plant.—The following calculation exhibits, in a tabular form, the advantage of a close plant. The first column gives the distance between the drills; the second that between the single plants in the rows; the third shows the number of roots per acre; while the fourth column gives the yield per acre on the assumption that each root weighs but 1 lb.:—

Inches.	Inches.	Roots.	Tons.	cwt.
15	6	69,696	31	2
18	9	38,720	17	0
18	12	29,040	12	19
18	15	23,232	10	7
21	18	15,004	6	12

What Manures are suitable.—Another lesson taught by these trials relates to the manuring of the crop. With your improved strontia process, by which the sugar is directly precipitated from the beet juice, no hesitation need now be felt in using superphosphate of lime, nitrate of soda, and other artificial manures suitable for sugar-beet. The increase thus caused of saline matter in the roots no longer interferes with the extraction of the sugar. Farmyard manure, however, should never be applied directly to the sugar-beet crop, but to that which precedes it. Where it has been used, especially in the spring, the roots have been uneven in size, coarse in quality, and much fanged. In light soils and dry seasons farmyard manure may help to secure a tolerable yield, but at the sacrifice of almost every desirable character in the root.

Land must be Clean.—A third lesson to be drawn from these experimental trials relates to the *cleanness of the land*. Weeds, especially couch grass, have sadly diminished the yield of roots in not a few cases.

Other Directions for Cultivation.—Many other points as to cultivation might be noticed did space permit. In the printed instructions issued by you on the subject of sugar beet growing, emphasis was laid on the importance of thick sowing; of early thinning and careful singling; of earthing up the exposed part of the roots; of cutting off any "bolted" or runaway stems; of selecting the proper time for pulling the crop; of drawing without wounding the roots; and many other details of cultivation. It is to be hoped that, in the future, these necessary directions will be followed faithfully, and that a strict uniformity of practice will prevail.

Proofs in favour of Sugar Beet Growing in England.—Aware, as I am, that there still remains much scepticism amongst well-informed and even amongst scientific men interested in farming, as to the possibility, in average seasons, of producing in this country a crop of sugar beet having a high proportion of sugar, it may be well to give further proofs of the soundness of the position taken up by the advocates of English sugar-beet growing. Putting on one side the older and better-known examples of successful trials of this plant, I will begin by citing the experiments made under your auspices in 1884 in Surrey, Berks, Oxfordshire, Middlesex, Northamptonshire, Lincolnshire, Staffordshire, Worcestershire, Warwickshire, Suffolk, Norfolk, Cambridgeshire, and Essex and also in co. Wexford, Ireland. We have between thirty and forty analysis of fair average parcels of roots grown in different localities and under conditions which, for the most part, cannot be regarded as favourable. * *

Experiments at Rothamsted, 1871-1875.—The Rothamsted experiments of Messrs. Lawes & Gilbert (1871—1875) are not less confirmatory of the value of sugar beet in this country as an industrial crop. With dressings of 5 cwt. per acre of nitrate of soda, on land which had received no manure for eighteen years previously, 21½ tons of roots per acre were obtained, the percentage of sugar in these roots being 11. Vilmorin's green-top white Silesian beet was the variety grown at Rothamsted. It must not be forgotten that several improved sorts of sugar beet are now at our disposal. * * * *

Value of Sugar Beet as Cattle Food.—The limits of my space forbid further enlargement of this report, although there are many topics connected with your important undertaking on which I should have been glad to dwell. But I cannot refrain from adding a few words as to the *value of sugar beet as cattle food*. Several of the farmers who have grown these roots for you in 1884 have been glad to use a part at least of the crops for feeding their stock; the results have been most satisfactory. Chemical analysis explains the superiority of sugar beet over other roots for feeding purposes. While mangolds commonly contain 90 per cent of water, and swedes and white turnips often more, sugar beets will generally be found to average about 81 per cent. Thus a crop of sugar beet, even though its gross weight may not be much more than half that of other kinds of roots, will contain quite as much solid nutritive matter. Moreover, it will present the further advantage of containing less of those saline matters which, without being of use in animal nutrition, tend, by their removal from the soil, to its exhaustion.—A. H. Church, M.A., F.I.C., sometime Professor of Chemistry at the Royal Agricultural College, Cirencester.—*Field*.

Woodlands in England.—Sussex formerly included six forests within it confines, and it still possesses a large area of woodlands and coppice than any other English county. The growth of hops occasions a market for underwood and promotes good management. The total area of the county of Kent slightly exceeds a million acres; hops cover 42,000 acres, and the extent of woodlands and coppices is about eighty-three thousand acres. It is worthy of note, too, that in Kent, underwoods are cultivated expensively but profitably on land worth 30s. an acre to rent, while in Scotland woodlands generally have been created upon barren moorland, worth nothing to plough, and only a shilling or two for grazing. In Sussex the woodlands cover 113,000 acres, the hops between nine and ten thousands acres, the total area of the county being 931,000 acres. Hampshire is another county well provided with woodlands, of which it has 105,000 acres, with a total area as great as that of Kent. These are the three best wooded counties in England, having from 10 to 12 per cent. in wood and coppice, while Essex, with its one million and odd acres, has only 27,000 in woodlands or about 2½ per cent; many other counties having much the same proportion, and England generally having about 1,500,000 acres of woodlands, and a total area of 32,597,398 acres, the percentage of woodland amounting therefore to about 4½.—*Field*.

COST OF PRODUCTION OF TEA IN CEYLON.

We have been reminded of what we, for the moment, forgot when writing on Mr. Rutherford's valuable figures (see page 729) that all home charges are fully covered by exchange. The remaining items our authority estimates at

Weeding, pruning, upkeep of roads, paths, drains, &c. ... 10 cents per lb.
Superintendence ... ... 4 ,, ,,

This is within 1 cent of our calculation, with the home charges adjusted as above. Tea, therefore, which sells for 60 cents per lb. wholesale at Colombo can be grown and manufactured for 30 cents per lb. Out of the resulting profit of 30 cents per lb., must be paid interest on cost of land, money borrowed, &c., according to the varying circumstances of each particular case. Of course, in calculating capital expenditure, it will not be fair to calculate all the back expenditure on coffee estates converted into tea plantations against the new product. In many cases the coffee estates ceased to have any value and the planting of tea amongst and to supersede the coffee, may be taken as imparting a pertectly new value to the land. There will be the cost of roads and drains in most cases and the effects of manuring in some cases to be charged against the results of tea cultivation, but it is impossible to give even approximate figures for cases which must differ so materially. As a rough guess, let us deduct R50 from the sum of R150 per acre we calculated in our last, as the profit of an estate producing 500 lb. per acre. There will still remain R100 per acre of absolute profit, provided tea sells at an average of 60 cents per lb. It seems evident, therefore, that where an average yield of about 500 lb. per acre per annum of good tea can be made, the enterprize cannot but be a paying one. How India (and Ceylon) teas are superseding those of China, will be seen by the articles we publish (page 732) respecting the once celebrated teas of Foochow.

While writing, we received a letter from the superintendent of Abbotsford, (see page 739) giving wonderful statistics of yield, on this elevated estate, for the early portion of this year. We may add that quality is not sacrificed to quantity, for, plucking is rigidly confined to the bud, the first developed leaf and half the second leaf. The prospects are that the average of 506½ lb. per acre obtained in 1884, and which has sold at an average price of about 1s 3d per lb., will be very appreciably exceeded in 1885. We need not say how readily we shall publish equally encouraging figures from other estates. B low we also give the dark side of the shield as painted by an Assam planter.

POSITION OF TEA PLANTING IN ASSAM.

(*Extract from a letter from an Assam Planter.*)

I am so placed at present, that, even if I wished to go to Ceylon, I could not do so ; nor have I sufficient faith in tea to embark any more money in it.

The prices are so low, and there is so little probability of any rise of importance, that the margin of profit is very small, and in most concerns there is no profit at all.

I have had 10 years' experience of tea, and may mention that 500 lb. per acre is a good average even in Assam, which province cannot be approached in yield per acre.

Anything much above 500 lb. per acre is very rare indeed and cannot always be kept up. By the time a lb. of tea is sold in London the cost of the same is usually one shilling even where every reasonable economy is practised, and the average price of tea per lb. to the producer is very *little* more.

If you look at the share-list, you will see that very few companies pay any interest all.

[The above contrast, in every way, reached us as we were summing up figures to show that in Ceylon a good, very good profit can be derived from 500 lb. an acre selling at a less average than 1s per lb.—Ed.]

CEYLON UPCOUNTRY PLANTING REPORT:

SAD EFFECTS OF THE DROUGHT—POVERTY-STRICKEN AND STARVING SINHALESE—WORK ON TEA ESTATES FOR SINHALESE—LABOR OFFERING—ADVANCES—EFFECT OF THE DRY WEATHER ON YOUNG TEA—VANILLA CULTIVATION : PROFITS TO BE MADE—COFFEE PROSPECTS—THE ELKADUWA TEA ROLLER.

2nd March 1885.

These dry times are telling on everyone. We had a little rain last week, but just enough to make us wish for more, and one would fancy it were the beginning of January instead of March, so strong and chill does the N.E. wind blow. The paddy crop is going to be very light, I learn in some places it has done no good at all, and the natives are at present not in a position to stand a failure of crop without assistance from without. Already, I am told, the Government is supplying rice to the Sinhalese in the Dumbara Valley, and ere long there will be more and as urgent demands from other places. In going through the villages, it is quite distressing to see how poor the people have become. Squalor visible everywhere, and the paddy-fields, except where there is a plentiful supply of water, a sad enough sight to look at. No coffee in these days to fall back on : what native gardens or trees remain are as barren as the seashore, unblessed with either leaves or a promise of fruit. There is one thing, however, which helps the impoverished Sinhalese, the work they can get on tea estates. Someone was telling me of a large batch which has left the Kandyan district to find work on the estates about Awisawella, and you hear of others travelling considerable distances to do the holing work in new clearings.

Those however who know most about the Sinhalese villagers say, that hard as is their lot at present, there is yet before them a pinch severer than any they have yet experienced. I cannot from my own knowledge say if this be a fair forecast of the future, although I heartily wish it may prove incorrect. Gangs of coolies keep floating about, wanting employment. Many are willing to engage without any advances, or an indefinite promise of having the matter considered at some future time ; some however stick out for cash down, and perhaps get it. I know of one estate which had not a cooly at the beginning of last month, and has sixty now without advancing a cent.

Yet some people must have been giving big advances. A kangani offered me thirty men the other day ; he could increase the force to one hundred he said, and when we were coming to closer quarters, he asked me to look at his "tundu," in which was written that on payment of R540 ! bearer and his coolies would be paid off. That certainly was a chance for somebody. He may have got employment since then, but he didn't just at that time.

Some of the young tea about here which was planted last year does not look as if it appreciated this dry weather at all, especially that planted in the N. E. Still, all things considered, it is holding out wonderfully well. The S. W. last year was such a miserable failure that it is rather rough on the tea, this long-continued drought, for, although we had some rain last week, it did not damp the

ground an inch deep. A good soaking would be so grateful at present.

I saw some very good vanilla at Pallekelly lately which was yielding a fine return of pods. It evidently wants a lot of care in preparation, but then the price is such a fancy one—as high as 30s a lb. for the best quality—that there is an ample reward for all the attention which may be bestowed on it. But the best sample of vanilla which I have ever seen is that grown by Mr. Wright in Colombo. There the plant is strong and succulent, and the pods are equally large and fine. It is a plant which wants care and regular attention, responds to manuring, and gives a good return. It is a sort of thing which many people might grow in their gardens, and that profitably.

In California, where the small orchard system is in vogue, ladies have done well for themselves in grape growing and raisin manufacture, living comfortably and laying part by for the inevitable rainy day from the proceeds of their lot; and it seems to me, that, in the cultivation of vanilla, there is a field for the energies of a similar class in this country, who at present do not find it very easy to get ends to meet even with the strictest economy. If carefully and steadily attended to, a very small patch of vanilla might yield as much as R500 a year! but it wants both care and attention, and wont do without it. The secrets of its cultivation are easily learned.

I hear from Badulla that the coffee prospects there are very very poor. Other places are better, but on the whole there is nothing that I know of very bright; and as for the prices at home, they are past speaking about.

In regard to the improved tea roller on Elkaduwa of which I wrote in my last, I should be very sorry indeed if I have given the wrong man credit for the improvements, as suggested by your correspondent "Kamrup." There is the possibility of the same idea having occured to the manager of the Elkaduwa group as to Mr. Fleming, and from what I can learn this is really how the thing stands. I suppose I was wrong in calling it a hand-roller, seeing that it was attached to a water-wheel when it accomplished the tabulated work you have already published. Of course it could be driven by hand; but I learn that it is not so certain that the same result could be got from it by manual labour, as was obtainable with water-power. I am obliged to "Tell Everything" for bringing out this fact, which I had overlooked, for it is well that we should know exactly what a machine should do, and how it does it. PEPPERCORN.

SUGAR, TOBACCO AND HEMP IN THE PHILIPPINES.

(*Translated for the "Straits Times."*)

By last advices (March) from the Philippines, there was every prospect of sugar growing in those islands being relinquished by many planters, and tobacco continuing to fall off both in quantity and quality.

Neither in hemp another of our leading produce articles, has there been much business done. When prices were fluctuating, speculations upon a large scale were set on foot in hopes of a rise, until a sudden fall turned the expected gains into losses. It is only cautiousness and regularity in business transactions, under the guidance of long experience, that can yield any profit to make up for the toil of those who by trading in the produce of a country, aid in furthering its well being. This fibre has greatly improved in quality in some producing districts. In others the quality has remained stationary and in a few it has fallen off.

FAIR TRADE AND THE DUTY ON TEA.

We append an extract taken from the London *Evening News* which, as developing an ingenious attempt to introduce Fair Trade under the shield of Imperial Federation, may be of interest even to readers in Ceylon :—

FAIR-TRADE.

IMPERIAL FEDERATION AND FAIR TRADE.

We take the following from the columns of the *New York Herald*, and we leave the head lines "Threatening Our Trade," &c., as they stand in the original:

THREATENING OUR TRADE

WHAT MAY FOLLOW THE FEDERATION OF THE BRITISH COLONIES;

PROTECTIVE CUSTOMS UNION;

WHY CANADA DOES NOT ASK FOR RECIPROCITY.

The telegraphed accounts of Sir John Macdonald's speech at Toronto on Wednesday on the subject of reciprocity will excite no surprise among these who are aware of the secret political movements both in England and Canada during the past six months. Canada, which for years past has been seeking a new reciprocity treaty with the United States in the lines of the old treaty of 1854, now, at the bidding of her Premier, sees even the fishery clauses of the Washington treaty expire without an effort on her part to renew it. This is remarkable in view of the fact that Canada is not prosperous, and sadly needs the market for her fish which the United States affords, but which will be closed against her on the 1st of July next. A well-known Canadian who has recently returned from England, and who is in a position to know all the facts, explained this apparent apathy on the part of Canada to a representative of this paper in a way which makes it very clear, and which will probably cause some of our business men to open their eyes.

RECIPROCITY.

"Reciprocity!" said he, laughing, when the subject was broached. "Canada does not want reciprocity—at least not such a treaty as we would be likely to get from the United States. We would be willing to have a free exchange of natural products, agricultural produce and raw material, but not of manufactured goods; and the United States would not be likely to consent to a treaty which would not admit their manufactures free into Canada. But we don't want a reciprocity treaty anyway. We have a much bigger scheme in view."

"What is that?"

"Why, Imperial federation. What do you suppose took Sir John to England last October, but to talk over this scheme with public men in England and prepare for the new political movement? Sir John is an old man, and does not make winter voyages across the Atlantic for amusement."

POLITICIANS' WANTS.

"But there is no demand in Canada for Imperial federation?"

"No, and there was none for confederation twenty years ago; but when the politicians made up their minds that it had to come it came, and the same thing will happen now. In England there is a cry for some action on the part of the Government for the restoration of commercial prosperity. In the present frame of mind of the English people no Government would dare to go to the country and say that it was doing nothing to remove the existing depression. Already the Tories have taken up the cry for 'Fair-Trade,' and with that they mean to force the hand of the Government or to oust them. In either case Imperial federation is sure to come." "But what good will Imperial federation do to the depressed British tradesman?"

At this the Canadian, who is one of the most polite of men, almost whistled, but rapidly recovering his dignity he continued:—"Imperial federation means a customs union of the mother country and all the colonies of the Empire, and the imposition of a tariff on the products of all nations which place a duty on British and colonial goods. At present most of the nations of Europe have protective tariffs which greatly restrict British trade. England buys from them but cannot sell to them, and but for the new markets she is constantly opening up among half civilized nations would be ruined. England

buys nearly three times as much from France as she sells to that country, and the same is rapidly becoming true of Germany.

TRADE WITH AMERICA.

"With the United States matters are still worse. In 1881 your country sent more than 500,000,000 dols. worth of goods to Great Britain and Ireland, and purchased from the latter less than 150,000,000 dols. worth. It is very clear that this kind of trading cannot last much longer without ruining some one, and the English people have nearly made up their minds that it is time it should be stopped. They say if the United States will not buy from us we will not buy from them, but we will form a customs league with our colonies and keep the trade within the Empire."

"But do the colonies produce everything that England needs?"

"Everything; they embrace more than seven and a half-million square miles and have a population of about three hundred million souls. They include territory in every climate and in each of the great continents. There is not an article that England requires that cannot be produced as cheaply in her colonies as in any foreign country. Look at the list of British imports. The six principal articles are flour and grain, raw cotton, wool, sugar, wood and timber, and tea. To these should be added other food products, such as live animals, meats, eggs, and fish. As for flour and grain India, Australia, New Zealand, Canada, and Egypt, which is virtually a British colony, will supply England with all she needs. Speaking as a Canadian, I may say that our exports of grain to the United Kingdom could be increased threefold in a couple of years. The surplus of wheat in Manitoba for export this year is six million bushels, and in three years it will be sixty millions if the scheme of Imperial federation is carried out, as it will be. I expect to see the day, and not a very distant one either, when not one bushel of grain will go from the United States to England."

AMERICAN COTTON.

"But can England do without American cotton?"

"Oh, yes; I know that there is an impression to the contrary, but it is not correct. Long stapled cotton can now be produced better in the Southern States than elsewhere, but that is no reason why this should always be so. India now produces a great deal of cotton for the English market, and could produce much more. Cotton is now grown in Queensland with success, and the whole of Northern Australia is a cotton growing region. Cotton is also grown in the Fiji Islands, in Natal, and largely in Egypt, which sends annually about 30,000,000 dols. worth to England. The production in all these countries could be increased to meet the demands of England's cotton mills. As for the other articles which England imports you will hardly need my assurance that all the wool, sugar, meats, and timber that England needs can be produced in the British colonies. Tea is now grown with great success in India, the export to England being upwards of 16,000,000 dols. and the area of production could be increased to almost any extent. So you see that all that England needs is to be found within the bounds of the British Empire."

INDUCEMENT TO CANADA.

"But what inducement is there for Canada to enter such a customs union as you speak of?"

"Why, every inducement. Take the single article of lumber, England annually imports about 70,000,000 dols. worth, of which less than 20,000,000 dols worth goes from Canada. Under Imperial federation all, or nearly all, would go from Canada. Under the proposed scheme the exports of Canada would increase threefold in lumber, grain, animals and their products, minerals and fish, for in connection with the other British colonies, she would take the trade that is now possessed by the United States. England and her colonies are now your best customers. Three-fourths of the exports of the United States now go to them, but all this will cease under Imperial federation, and you will have to find a market elsewhere. I see your Government is making great efforts to obtain more trade with Spain, South America, and St. Domingo. It would, perhaps, have been as well to pay some attention to the trade with the British colonies. The St. Domingo trade will be but a poor return for the loss of the trade of Canada. Perhaps you think that these ideas are impracticable; you will know better presently. Some of the ablest and best minds in England are enlisted in this movement, which is destined to produce a greater commercial revolution than anything that has happened since the repeal of the Corn Laws. After all, England in adopting this policy, will only be using the weapons of her rivals, but in a larger field and with more deadly effect."

It has been shown recently how under the present system of Free Trade the British consumer stands in much the same position to the fruits of the toil of the producers over the face of the earth that the British landlord is shewn by Mr. George to hold towards the British worker. With the new Franchise Bill actually passed, by virtue of which the British consumer becomes *de facto* master of the position in regard to future legislation, at least for the United Kingdom, it is hardly credible, whatever might be the merits of the arguments *pro* and *con.*, that he will consent to part with one iota of the advantages of the position secured to him by the freedom of trade with all producing countries.

It may be assumed then that the notion of an Imperial British Zollverein is little more than a brilliant dream, not likely to be realized in the future. On the contrary, from amidst the stir of expectation caused by the passing of the new Franchise Act, there arise some notes which portend a change rather in the opposite direction. In the city of London posters are to be seen explaining "How we are robbed." "The rich man's shilling's worth of champagne is taxed at ½d. The poor man's shilling's worth of tea is taxed at 7d." Simultaneously a cabinet minister is heard speaking ominously of a necessity of the revision of the system of taxation, his remarks pointing in the direction of heavy increased direct taxation on accumulated wealth.

Apart from general political considerations our Ceylon planters will rejoice to think that attention is being drawn to the position of tea as a source of revenue. By the course of events it has drifted into being the one mainstay of the British Customs outside of alcohol and tobacco. In 1884 the duty collected on tea amounted to £4,268,448, a sum which must be fully half the wholesale market value of all the tea consumed during the year in the United Kingdom. The leaps and bounds in the revenue which so gladdened the heart of the present Prime Minister and enabled him in years gone by to make nearly a clean sweep of the articles in the Customs Tariff, and which even ten years back were sufficiently high to allow Sir S. Northcote to abolish the sugar duties, unfortunately died to nothing before the turn of tea came—and now for 10 years past in this country of boasted free trade there has been the spectacle of an import duty on *one* article of almost universal consumption, increasing each year, as the price of the article has fallen, in proportion to the value, till it stands at the present time as a tax of 50 per cent.

Strangely enough there has as yet been found no one among these interested, bold enough seriously to attack so glaring an anomaly. No doubt the difficulties in the way of the repeal of this duty at present are such as to make the weakest Chancellor of the Exchequer obstinate. Imperial responsibilities all over the face of the globe are daily increasing, and with increased responsibilities come inevitably increased expenditure. At home the nascent Democracy ever calls on the leaders of affairs for more ample provision in the way of what has been aptly termed "grandmotherly" government, while on the other hand day by day the people are learning sobriety and decline to contribute the same sums as formerly to the revenue on wines and spirits and other alcoholic drinks. This is clearly not a favourable time for the abolition of productive duties.

Nevertheless the fact remains that the tea duties are plainly indefensible. And it may be confidently stated, that, had the Planters' Association of Ceylon been as deeply interested in tea from the beginning of its history as it has been in coffee, the duty on tea would not at this present time bear so overwhelming a ratio to the value of the article.

To those, should there be any, who oppose any movement against against the tea duties on the ground of the hopelessness of the position, the answer is that experience has shown that only by pressure in season and out of season can any effect in a matter of this kind be produced. Let the course of events in regard to the reduction of the coffee duties be borne in mind. And as to finding the means whereby a loss on a change in the tea duties may be recouped, that is a question not for the planters who suffer by the present anomalous position, but for the politicians who have brought it to pass.

THE REV. J. E. TENISON WOODS ON THE MINES AND MINERALS OF THE MALAY PENINSULA.

The report of a lecture so entitled, delivered at Hongkong, intensifies our desire that the able Roman Catholic priest who has done so much for practical geological science, first in Australia and nowin the Straits of Malacca, could be induced to visit Ceylon and report on its geology and mineralogy. We do not think he would confirm the views of the author of a notice of the geology of Uva who speaks of "trap" rock in an island where, in the judgment of most scientists, there is no trace of volcanic action, but he would probably set at rest the question of the existence of coal or other valuable minerals. We quote from the *Straits Times* as follows :—

From what he had seen and all he had read of the tin deposits of the Malay Peninsula, he concluded that they were, without exception, the richest in the world. He was aware that there was a prevailing impression here that this was not the case, but still it was perfectly true. There was no more widely distributed deposit of tin than in the Malay Peninsula, at least not of that particular kind of tin deposit which was termed stream tin. They were very widely spread and the deposits in themselves were practically inexhaustible. The lecturer proceeded to show by a map the peculiar formation of the peninsula remarking that its shape was singularly developed. There was an immense range of mountains, a few of which had been explored, and some of which he was the first to explore, while others, much higher, had been effectively explored by a French gentleman who had since gone home. Some of the mountains reached a height of 10,000 feet, and there were, he believed, some even higher than that. These mountains, in about the centre of the peninsula, began to decline until they came to a part at which there was so little elevation that boats might be dragged from one river to another on the opposite side. It was there the richest part of the tin deposit was to be found ; there had been the greatest disturbance, and there was the greatest mineral richness. In a disputed country between the territory of Perak and Siam there were tin veins. He should speak briefly about these veins, and he might say that this was the only case he had met with where there were veins of tin in the peninsula ; elsewhere, in the south it was in alluvial deposits. This was a very important thing to bear in mind, because he had met in Hongkong several persons who had asked him if there was not something peculiar about the tin deposits there. To these he would answer that there was nothing peculiar at all about them, they were exactly like stream deposits all over the world—no difference. He had been asked something about pockets ; he knew pockets were a subject in connection with mines about which people were particularly tender—(laughter),—but there were no such things as pockets as they were generally understood which made them different from deposits in other parts of the world. The deposits of tin had been accumulating for ages from the wearing down of the granite rocks. He was also asked if there were no main sources from which the tin was derived, and he answered "No, nothing of the kind was found in what was known as stream tin as far as his experience went." It was most important to bear this in mind, that wherever stream tin was discovered, veins were not found, and where veins were found, there was no stream tin. Had time allowed he could have explained the reason of this, but he had now to confine his attention to what stream tin was. Let them suppose that they had in the mountains of the Malay Peninsula the representation of those forces which had upheaved their rugged summits, which had in course of time, through the slowly acting forces of the weather, worn them into peaks and gullies as they are now seen. The rev. gentleman said his hearers must excuse him if he appeared to enter into explanations of things that seemed self-evident ; as he proceeded the reason would be apparent. This decomposing and wearing down of the granite by the action of the weather was owing to the iron contained in the felspar being easily rusted,* and thus the granite was disintegrated till nothing was left to represent it but heaps of fine sand. With this sand there was washed down by the force of water grains of tin that had been contained in the granite. Whatever was contained in the granite was washed down into the valleys, and a great deal of alluvial granite was carried out to sea in the form of a fine mud which discoloured the water, but was finally deposited on the coast, and was the cause of those immense mangrove flats and mud islands that were to be found about the Malay Peninsula on the west coast. The lighter portions were carried away the furthest, and the heavier portions remained at the foot of the hills, and it was with the latter that the tin was found. It was found at the bottom of the deposit, and it might be said that if it was thus deposited it must have been only the surface of the granite which was rich in tin, and it was washed down first, and subsequently covered with alluvial sand. But it would not be right to argue in this way. The granite and tin had been mingled together so generally that probably a very minute examination of the granite would have been required to perceive the tin it contained, except in exceptional instances, where it was found in little streaks, and bosses, and lumps. As to the reason of the tin being gathered together in the lowest portion of the deposit, cassiteria was more than several times the weight of common quartz sand, and sank rapidly, but its weight alone would not account for the fact. The tin was found in some ancient stream bed—not the mere breadth the stream now occupied, as in the course of ages the stream would have travelled over a wide valley. The mud it brought down obstructed its own course, and caused it to constantly change its channel, and it was carried backwards and forwards across the valley and the deposit was washed much in the way it was done

* This fact of iron being a decomposing agent has an important bearing on our ferruginous tea soil as well as on the change of felspathic gneiss into fertile laterite. Whether hard rock or stiff clay, what is wanted to ensure decomposition is full exposure to the atmosphere. The clay should be opened with the fork.—ED.

by artificial means. Every time the stream changed its course it washed the sand from the alluvial deposits, and turned it over and over again, allowing the water to pass through the midst of it, so that the tin was gradually left, and the sand, or lighter portions were carried away. It was in this way that the tin came to occupy the lowest portion of the deposit. It was covered with a deposit of alluvium sometimes as much as 30 feet in thickness, in others as much as 50 feet, but usually much less, sometimes as little as ten feet. The thickness or richness of the tin deposit bore no reference to the thickness of the deposit above it. It was merely a matter of chance, only he thought it might be inferred that where there was a thick deposit of alluvium over the tin, and the tin was not very thick, the deposit could not be of a very rich character. The audience would now understand how stream tin occurred. What occurred in Perak occurred also in Australia, and in all mines he had visited where stream tin was worked. There seemed to be an impression that the stream deposits in Perak were poorer than those in other places, whereas the fact was that if anything they were richer. If people thought, too, there was a larger deposit of sand over the tin that was a mistake. It would be found that in some cases there was more in Cornwall, and it was so also in Australia. Probably in Australia the tin deposits had not been fairly worked, for on account of labour being so very dear none but the richest mines were worked and these were worked very differently from the mines in Perak. People asked him, again, how it was that the result of tin mining in the Malay Peninsula was unsatisfactory if the mines were as rich or richer than those in other parts of the world. That depended upon economical considerations with which he could have nothing to do, but still he could form his ideas upon the subject, which might be right or might be wrong, for clergymen were not as a rule very good men of business and when he told his hearers what he thought about the matter at the termination of his lecture, they might take his remarks for what they were worth.

The lecturer then went on to describe granite as, in his opinion, the result of pressure and superheated steam on stratified rocks,† and he stated that tin was always found in stream beds at the junction of the paleozoic rocks with granite indicated by a fiery red soil. Then came the practically important part as to the best system of mining :—

Then another thing was to be said about the deposits of tin. They were not to be worked on ordinary mining principles, because the alluvial soil was at most only some fifty feet thick, rarely so much, and more often only fifteen or sixteen feet. Under these conditions they could not go tunnelling and burrowing and putting in operation all those mining apparatus found so useful where great depths below the surface had to be reached. Pratically they could do nothing but strip off the alluvial soil, and on coming to the tin extract it from the deposit by means of washing. That was the simple process of mining in the Malay Peninsula. He did not know of any place where similar deposits could be worked otherwise unless they were very deep, and then they could not be worked profitably unless they were unusually rich. He did not think that had been recognized by the Europeans concerned in the Malay Peninsula. It had been assumed they could sink shafts and run galleries and tunnels. That was sure to lead to failure. Even if they could do so they were sure to meet with large granite boulders, and as they could not use dynamite where the working was so shallow they would have to work round the rocks and leave a good deal of valuable tin in doing so. No doubt it was very gratifying to our national vanity to be able to show the Chinese what could be done with machine appliances, and if it were merely a benevolent undertaking that would be very interesting, but in practical work it led to a great deal of unnecessary expenditure and could not result in any great gain to those interested. His impression was that the mistake had been in not mining as the Chinese do. They strip off the soil in the most economical manner, they wash their tin deposits without any great appliances, and in that way they make their money. Probably it would be said the Chinese have advantages which we do not possess. This was perfectly true, and it seemed to him, if he might offer a suggestion—and this was where he meant his ability was not sufficiently trustworthy—he would suggest that the mines should be carried on by Europeans on the tribute system rather than by the use of appliances which from the nature of the case could not be expected to pay. He would give an illustration of this. In the early days of gold mining in Port Philip some of the mines gave very large dividends. One of the most prosperous for a time was the Clunes mine, but as they went deeper and deeper the quartz got poorer until at last it was found the mine did not pay. The shareholders got alarmed, and some of them were for selling off and realising their property as soon as possible. However, better counsels prevailed. Those who understood the matter said :—"Look here, these miners are bringing up all sorts of stuff for you to crush in your mills. They do it because they are paid so much a ton, and they will go on doing so without reference to anything but bringing so many tons to grass." The miners were then told they could take so many cubic yards, they could take all the gold, and the company would pump and wind for them. The consequence was that the Clunes mine, instead of becoming a loss, was soon returning nearly as large dividends as it did previously. He thought the only way to mine successfully in Perak would be on a somewhat similar principle. Let the tributaries be the Chinese, who knew how to work the mines, and let as few Europeans as possible have anything to do with it. The climate was bad, the privations great, and the Europeans employed deserved to be paid good salaries ; but let there be as few such as possible. He would not detain them further. He could say more, but what he had said he hoped was sufficient to make clear to them that mines in Perak are no exception to mines elsewhere. They are rich ; they offer favourable fields for the employment of British capital ; but they require care in the working. In the end they cannot fail to yield satisfactory results. (Applause.)

Canker in Fruit Trees.—Canker in fruit trees is considered by most cultivators as caused by unhealthy root-action. For many years I have each season had something to do with the renovation of fruit trees, and in many cases had to deal with canker in its worst form ; but wherever lifting the roots from unhealthy quarters was practised, the wounds well cleaned with the knife, and a good coating of clay and lime painted into the wounds, the trees recovered and did well. By inducing the roots to grow upwards into wholesome mulching disease disappeared, and the wounds healed. I can point to many cases where such manipulating was practised, and the trees are now healthy. This experience dates back from the present time to the earlier days of my gardening life while an under gardener in the south and west of England, and I will refer to a few cases, which is better than theorising. I cannot at any time point to a case where I could have blamed insect agency as being the direct cause of canker, but I have very often seen the disease accelerated (after it was established) by insects harbouring all over the wounds, American blight being the most formidable enemy to contend with.—*Journal of Horticulture.*

PHYSICAL GEOGRAPHY OF THE MALAYAN PENINSULA.

As some remarks of mine on the mountain system of the Malayan Peninsula have already appeared in *Nature*, perhaps the following summary of the results of ten months' explorations in the State of Perak will be interesting.

The State of Perak is comprised between the sea (Straits of Malacca) and the main central chain which runs along the centre of the peninsula. Its boundaries are, roughly north, the River Krian; south, River Bernam; west, the ocean; east, the main central chain. The geology may be chiefly described as consisting of—

(1.) An immense granite formation, rising into extremely sharp and precipitous parallel ridges having nearly a meridional direction. This granite passes frequently into slates and schists. The prevailing colour is blue.

(2.) A Palæozoic formation of slates, mottled sandstones, and clays, forming outliers or detached portions. It is found most abundantly at the foot of the ranges, whence it usually dips away conformably to the slopes of the hills and mountains. It has evidently been subject to great denudation.

(3.) Limestone in detached outliers, or isolated hills of precipitous character, showing much denudation. It is stratified or crystalline. No fossils have been found yet, but is probably of Palæozoic age. From its wide extension throughout Perak, where it crops out in so many places, it may have once covered the whole of the granite and Palæozoic clays.

(4.) Drifts and alluvium from the ancient streams and river beds. These are formed of the material from all the preceding deposits. All the tin deposits of the country are in these drifts. The ore occurs in a manner very similar to the alluvial gold in Australia, that is to say, in "leads," which are the ancient or modern river beds.

Above these alluvial deposits there is the usual alluvial surface soil, for the most part supporting a very dense vegetation.

The tin deposits hitherto found are all stream tin. No lodes have yet been worked, though there are some in the mountains round the sources of the Perak river. The ore is almost always cassiterite in small abraded crystals. It is of a peculiar blackish-gray or brown aspect. Any person with a little experience would be able to distinguish between tin sand from Australia and that of Perak. The former is rather rich in gems, such as sapphires, rubies, hyacinths, garnets, topazes, and zircons. I have never seen any in Perak; but there is a good deal of fluor-spar, tourmaline, and less frequently wolfram.

The most of the workings are on the western slopes at the foot of the mountains. I cannot recall any instances of mines on the eastern slopes, but the wash or drift seems to have been greater on that side.

The matrix of the tin seems to be in the upper part of the granite at its junction with the Palæozoic clays. In the lower part of the clay there is also a small quantity of tin.

In the drift the tin is always found in nearly the lowest levels, lying in one or two strata from one foot to five feet thick. It is mingled with fine drift sand and gravel. Its position is, I think, due to the repeated sifting and washing it has been subject to in the stream bed. But as it is generally covered by from ten to thirty feet of material destitute of tin, the inference is that only one part of the granite was very rich in the metal.

The stream tin deposits lie upon (1) kaolin clay, or partly decomposed granite; (2) granite; (3) Palæozoic sandstones and clays. In the latter case the stream has come from the denudation of a portion of the same strata on the upper slopes of the hills.

On the highest granite ridges, or those above 5,000 feet, there is found a distinct vegetation. Three or four of the genera are Australian (*Melaleuca*, *Leptospermum*, *Podocarpus*, *Leucopogon*), and two of the species (*Leptospermum* and *Leucopogon*) are common Australian forms. Similar facts have been observed in Borneo, but I have not heard that they had been observed in the Malay peninsula. Nothing of the kind is seen on the lower slopes of these mountains even 100 feet below the summit. This Australian flora may be the relics of an ancient flora, which once included the Eastern Archipelago. But it does not appear why the species should be confined to the tops of the mountains. They grow in a much warmer climate in Australia.

There are no table-lands in Perak; the mountains are all sharp ridges. There is not the slightest sign of any recent upheaval of the coast line, while the evidence of subsidence is equally absent. But the land is rapidly encroaching on the sea owing to the immense alluvial wash brought daily from the mountains in this land of heavy rains. Thus the shores are fringed with large mangrove swamps which yearly extend, and the Straits of Malacca form a shallow sea full of mud banks and shoals. The seas are consequently rather poor in certain forms of marine life to which muddy sediment is unfavourable.

Though the tin has been worked for centuries, only a comparatively small portion of the country has been worked out or worked at all. I consider that the deposits in Perak are practically inexhaustible. The mining industry is almost exclusively in the hands of the Chinese, who are almost the perfection of colonists for a country like this. Malays are not good miners. Gold is found associated with tin, but small, scaly, in sparing quantity, and only in one or two places.

There are only two instances known to me of the occurrence of recent volcanic rocks; one is in the Kinta River Valley, the other on the western face of a small group of mountains not far to the east-south-east of the island of Penang, and near the Karau River. The rocks appear to be basaltic dyes, but the thick jungle and surface weathering prevented a proper examination.

The mountain system of this native State consists of detached groups of mountains which cover the west side of this part of the peninsula, an almost continuous range close to the sea in the Straits of Malacca. These groups of mountains form parallel chains about thirty miles long, with a direction a little oblique to the true meridional line. Sometimes they are wholly detached groups, so as to allow rivers from the eastward to pass between them. Such an instance is seen in the ranges between the Kinta and Perak rivers. This group terminates to the north so as to allow the River Plus to pass to the westward and to the south so as to give an outlet to the Kinta. Both rivers join the Perak River, which flows round another group (Gunong Bubu), and then flows into the sea in the Straits of Malacca.

The islands of the coast, such as the Dindings and those off the State of Keddah (Pulo Leddas, Pulo Lankawi, and Pulo Buton, known as the Buntings), are probably portions of similar groups, and so are Pulo Penang and the attendant islands. These groups and those on the mainland usually run in sharp parallel ridges, variously modified by oblique spurs, which at times connect the main chains forming watersheds which throw off small streams north-east and south-west.

The following are the principal groups of mountains known to me, beginning at the south:—

Dindings Islands.—Off the coast in front of the Dindings river (*Dinding*, Malay for boundary or partition), lat. 4° 12′ N., there is a series of islands of moderate elevation not exceeding 1,000 feet in their highest peaks. They are granite, rich in tin, with a little fine scaly gold. They are densely clothed with jungle, and have fringing reefs of coral. I have visited three or four of these islands, and they are all of the same character.

On the mainland there is a cluster of hills called the False Dindings, from the fact that at a short distance they look like islands. These are also granitic, and tin occurs in the alluvial beds derived from them. They give rise to small rivers, such as the Dindings and its tributaries.

Gunong Bubu.—North-east of this group, but quite detached from it, is a series of parallel mountain ridges with a uniform trend of north-north-east. These ridges are eight or ten in number. The central one is the highest, culminating in Mount Bubu, a fine peak of about 5,600 feet elevation. All the ridges are granitic, with occasional patches of metamorphic schists, all more or less rich in tin. A remarkable character in this range is that all the ridges are extremely steep, and frequently interrupted by granite precipices of 1,000 feet and more. Gunong Bubu is only accessible in one or two places, the summit being

surrounded by escarpments of rock of great height.

Many small streams join the Perak River and the sea from this range. The Kaugsa and Kenas both flow into the Perak to the eastward. In an ascent made by me to the summit of Mount Bubu I was able to explore some of the sources of both these rivers, which afford a home to many a rhinoceros, but few other animals except monkeys (*Hylobates*, *Semnopithecus*, and *Macacus*). The rivers descend many hundred feet in a series of cascades, giving rise to some of the finest scenery in the Malay peninsula.

North of Mount Bubu this group of ridges falls away abrubtly, leaving a narrow pass (Gapis Pass) between them and the next group. This pass is about 400 feet above the level of the sea, and therefore too elevated to permit of any river outlet.

Mount Poudok.—In Gapis Pass, or rather at the eastern end of it, there is an isolated hill of highly crystalline limestone. It is an outlier of the great Palæozoic limestone formation already referred to. It is about 400 feet high, and quite precipitous. Its junction with the granite or Palæozoic clays is not visible. Its bright blue and red precipices crowned with dark-green jungle make it a singular and beautiful object, but there are many similar in the State.

Mount Ijau.—North of Gapis another group of ranges succeeds, culminating in Mount Ijau (Malay for green) at about 4,400 feet above the sea. The cluster of ridges appears to me to be of nearly the same dimensions as the Mount Bubu group, but not so high by 1,000 feet or so. I estimate that each group is from twenty to twenty-five miles long, and fourteen to sixteen broad, covering an area of about 400 square miles. This, however, is only a rough estimate formed from views I have been able to obtain from the summits of other mountains. I have not been able to examine personally the termination of the Mount Ijau group on the north. From the sea one is able to perceive a distinct pass like that of Gapis. It is probably about the same height, and does not form the outlet of any river from the eastern side.

Kurau Group.—North of Gunong Ijau is another group, which I do not know how to distinguish except that it forms the watershed of the Kurau River. Its highest point is a mountain which is also called Ijau by the Malays. I have not ascended the peak, but it seemed to me less elevated than Mount Ijau to the south.

Mount Inas.—What the Malays of Keddah call Mount Inas is the highest point of another detached group north of the Krian and Selama Rivers. I have been within a few miles of the foot of this mountain, and it seemed to me to be somewhat over 4,000 feet high, and the highest point of an isolated group of ridges.

Keddah Peak.—North of Mount Inas, in the State of Keddah, there is, close to the sea, a detached group of mountains, at the foot of which the Keddah River flows. Keddah Peak is the highest summit,—probably over 4,000 feet high. This is in what is called Lower Siam, in which I have only travelled to a very trifling extent north of the Krian River, the boundary of Perak State. In the north of Perak, near Patani, we have other groups of mountains. An Italian explorer named Bozzolo, who has lived many years in Siam, assures me that he has travelled round the Gunong Kendrong group at the head of the Perak, and that it is quite detached from any other hills.

Perak River.—The whole of these groups are sufficiently connected to prevent any drainage from the central range flowing directly to the west coast of the peninsula. Thus the Perak River, which has its sources in the Keddah and Patani Mountains flows to the southward for over 180 miles. In its course it is joined by two important rivers from the eastward, namely, the Plus and Kinta.

Plus River.—The Plus River has its sources in the high mountain groups east of Mount Inas, and in the main range. It flows round the southern end of a group called by some the Bukit Panjang Range, and then joins the Perak.

Kinta Ranges.—South of this junction is a group of mountains called by some the Kinta Ranges. This group is about twenty-five miles long. It is perfectly detached from all the others, having a generally north and south direction, but sending off spurs from its west side a little to the west of south. The group is entirely granitic, but on its lower slopes has thick deposits of limestone belonging to the formation already referred to, above and below which tin is worked. For about twenty-five miles this range separates the valley of the Perak River from that of the Kinta, which flows on its eastern side. The highest peaks rise to about 3,750 feet above the sea, and give rise to small streams which all flow into the Perak. There is a remarkable uniformity in three or four of the highest summits, which are about the centre of the chain, Mount Merah (red), Prunguin, &c. They are all within a few feet of the same height. From these mountains the range falls away gradually to the south, and sends off two considerable spurs to the south-west. Where it ceases the Kinta River joins the Perak.

Kinta Valley.—The valley of the Kinta River is about as wide as that of the Perak. The river flows, like the Perak, on the eastern side of the valley. The eastern tributaries are many and important. On the sides limestone granite and schistose slates crop out. To the eastward there are many detached hills of limestone fronting the main central chain. They form very characteristic features in the landscape, from their precipitous outline, and the brilliantly coloured faces of blue, green, and bright red rock. They are also distinguished by a different vegetation.

Perak Valley.—The valley of the Perak River is bounded by the groups of mountains already described on the west; on the east by the Kinta Range, and north of the Plus by the Bukit Panjang Range. The river flows on the eastern side of the valley; this is owing to the many spurs and outliers on the eastern sides of Mounts Bubu and the Ijau Ranges. It seems as if there had been much less denudation on the eastern than on the western sides of the range. This may be owing to the prevailing rains falling more abundantly on the western than on the eastern sides of the mountains.

As a consequence of this the tin workings appear to be, with little exception, on the western side of the ranges, where the waste and wash has probably been greater.

Batu Kurau.—Between Mount Bubu Range and Mount Ijau Range and the sea there are no hills except small outliers, mostly of Palæozoic clay, which have evidently belonged to the ranges. By north of the Larut River there is an isolated limestone mountain near the Kurau River. This is called Batu (stone or rock in Malay) Kurau. It is very similar to Mount Poudok in the Gapis Pass. It is quite unconnected with the main range, and rises out of the plain between the spurs which form the valley of the Kurau River. There is also a small detached range dividing the valley of the Krian River from that of the Kurau.

Main Range.—Of the main range I know but very little from personal observation, having only visited it at Goping, and at the limestone hills, where the tin is worked on the Diepang River. But I have travelled along the most of the Kinta Valley skirting the base of the range either on foot or in boats. I have also traced the valley of the Kampar River. The geology is like the rest of the country, mainly granite, slates, and limestone, with traces of basaltic rocks. The general structure of the range can best be judged from some of the mountains to the westward. It forms a most imposing boundary to the whole of the western horizon. In the north, about the sources of the Plus River, there is a mountain of rounded outline, probably over 6,000 feet high. The range there declines a little, with a somewhat serrated outline, but generally over 3,000 feet. At a point corresponding with the latitude of about the centre of the Kinta Range, or opposite the Gapis Pass, the chain increases in elevation to perhaps over 5,000 feet, and in the distance is seen a peak which must be over 8,000 feet high. I know no name for this hill, but it is the most distant mountain usually seen. South and west of this the chain rises into a grand cluster of peaks, the highest of which is over 7,000 feet. This is Gunong Robinson. It looks higher than the Sugar-Loaf Hill as seen from Gunong Bubu, but then it is much nearer. From Gunong Robinson the range declines to the southward, but is still a bold series of picturesque peaks, many of which must be over 6,000 feet. It has been asserted by more than one observer that to the south of the point where the range is lost sight of from Arung Pura, there is a high mount-

ain occasionally visible higher than any other in the main range, and probably over 12,000 feet. This I have not seen, but I am convinced that there are many things yet to be learned about the most elevated portions of this mountain chain. Seen from any point of view, it forms a magnificent mountain prospect. Its mysterious unexplored recesses are rendered more gloomy than any scene in the world from the dense forest and the masses of vapour and cloud with which they are always clothed. A few savage Sakies are the only inhabitants. I may add that perhaps in no country in the world is exploration rendered so difficult from the extraordinary thickness of the jungle and the steepness of the mountain ridges which unceasingly cross the traveller's path.—J. E. Tenison-Woods, Penang.—*Nature.*

A Wisconsin Farmer claims to have found a sure cure for potato bugs. His plan is to put one or two flax seeds in each hill of potatoes. He says that the bugs will shun it every time, and for ten years he has thus been successful in growing potatoes while others have failed.—Melbourne *Leader.*

Potash and Lime as insecticides are thus noticed in the Melbourne *Leader* :—"We have been favoured by Mr. Henry Stevenson with specimens showing the effects of the potash remedy for the woolly and other aphides, as well as upon the growth of the trees. It will be remembered that last year we gave the details of Mr. Stevenson's first experiment, whereby he completely cleared a badly infested apple tree of the aphis in a few months by the application of lime and potash to the roots. This tree, which remains almost entirely free from the insects, is now in perfect health, and making shoots that are already a foot in length. Accompanying this was a branch from a tree of French Reinette apple, which was also much infested with the aphis, though not so badly as the former. The mixture was applied to this about four months ago, and it is now clean, clothed with healthy foliage, and bearing a dozen apples on a foot in length, with a shoot a foot long on the end. Shoots from a peach tree, which was treated at the same time as the last, are also clean and healthy."

The Immense Economical Importance of Government Botanic Gardens, especially in young colonies, is well shown by the last report of the Curator of the Gardens in Brisbane. Omitting the distribution of ornamental trees, shrubs, &c., to the gardens of public institutions, as well as that of ornamental pot plants, we find that economic plants have been distributed on a very large scale. The demand for these has been unprecedentedly large, and no application is ever refused so far as it can be supplied. About 3,000 economic plants were sent out during the year; these consisted chiefly of various kinds of coffee, tea, cocoa (*Theobroma cacao*), cinchona, and vanilla. Grafted Indian mangoes and plants of the Brazilian nut (*Bertholletia excelsa*) have been given to likely growers, and the demand for the latter is so great that application has been made to the universal feeder of these institutions, Kew, for more. Besides acting as a collecting and distributing agency, the Brisbane Gardens do what is perhaps of even more value, viz., ascertain by experiment the conditions under which certain foreign plants will grow best in the colony. The most important trials recently have been with regard to cinchona, which, Mr. Pink shows, may by care in its early stages, be successfully cultivated in Queensland. The hop plant has been tried, and appears a success, 10 cwt. being the produce per acre the first season, while in England under similar circumstances it is only 4 cwt. Sugar is at present the staple of the colony, but no efforts are spared to discover new kinds elsewhere which may be better adapted to the place. Hundred tons of various kinds of cane, chiefly from Mauritius, were sent to planters during the year. Economic and valuable timbers also receive much attention, and the gardens have now ready for transplanting 20,000 trees of various kinds, including cedars, olives, silly oak, English oak, English ash, poplars, and chestnuts. The recent experiments have conclusively shown that Queensland can introduce among her staple produce-crops such valuable and remunerative products of the soil as coffee, hops, and cinchona. As an example of the care and labour devoted to the work, it may be mentioned that every method of cultivating the cinchona in Ceylon and South America was tried in the gardens without much success; and finally Mr. Pink was compelled to devise a method of his own, which proved successful.—*Nature.*

Transmission of Western Australian (Cut) Flowers &c., by Mail Steamer to Victoria.—The distance from King George's Sound to Hobson's Bay is about 1,540 miles in a straight line, and it, therefore, speaks well for the packing and transmission when I remark that the flowers were received in so fresh a state that one would suppose they had been gathered only on the day the packages were opened, instead of twelve days before that time! The plants, too, enclosed in a canvas covered box (exceptionally well packed) were found to be in the best possible state of health. So far as the flowers are concerned, packed them in damp moss in circular tins, such as would hold a pound weight or so of coffee, closed the lids and pasted the junctions over with paper, both to prevent the evaporation of moisture as well as to protect the contents from the action of the atmosphere. The following is the list:—

Banksia coccinea	Hovea ilicifolia
Boronia crenulata	Johnsonia lupuina
" elatior	Pimelea imbricata var. pilifera
" heterophylla	" sulphurea
Chorozema angustifolia	Ricinocarpus tuberculatus
Conospermum cœruleum	Tetratheca pubescens
Cosmelia rubra	Verticordia Fontanesii
Dampiera (species)	Xanthosia rotundifolia.
Hovea elliptica	

—*Gardeners' Chronicle.*

The Pruning of Fruit Trees.—The timely and judicious pruning of furit trees is the most important part of their cultivation, yet it is that part which recieves but little attention. When fruit trees have been neglected for some years it takes some time and labour to get them into form again, but when trees have been looked over carefully, every season from the time of their being planted, they will not require much annual labour to keep them in shape. The principles on which pruning is founded and its general effects are pretty well understood. If the stem and branches of a plant contain a hundred buds, by removing half of these the shoots or fruits produced by the remainder will be supplied with a greater amount of nutriment than if all had remained. On the other hand, when the whole of the buds of a tree are so abundantly supplied as to produce chiefly leaves or shoots without blossoms, then by cutting off a portion of the roots the supply of water is lessened, a moderate degree of vigour is produced, and instead of barren shoots blossom-buds appear. By these methods of pruning—now the roots and then the branches—the growth is controlled and fertility induced. If a fruit tree were not deprived either annually or biennially of a part of the wood or buds which it produces, its fruits would gradually diminish in size, and though the fruit might be more plentiful it would lack juiciness and flavour. All fruit trees grown in orchards should be mostly grown in the standard form, this being the natural form they assume, and in which they attain the largest size and produce the greatest quantity of fruit with the minimum of labour. Standard trees require only to be pruned to keep them in shape and to prevent over-crowding of the branches. Pruning is also resorted to for the purpose of adding vigour to feeble trees. Unfortunately, orchard trees receive, as a rule, very little attention in pruning. All cutting away of large branches in healthy trees should be avoided, and this can be done by making it the practice to examine them every season, when the superfluous shoots can be cut out. In orchards where pruning has not been regularly attended to, large limbs will sometimes have to be removed. Where this is necessary, the cut should be slanting, and the wound should be smeared with tar or some composition, or be covered with a cap of lead or zinc, to prevent the entrance of moisture. Tar-covered wounds, if surrounded by healthy bark, rapidly callus over, and are to be preferred to any other, unless the surface is very large. Trees with luxuriant growths, if yielding only worthless sorts, should be headed back and grafted with superior kinds; if too old, remove the trees, and plant better sorts.—*Gardeners' Chronicle.*

NATIVE AGRICULTURE IN CEYLON: "YOUNG JAFFNA."

When I say that young Jaffna must take to the plough, let me not be misunderstood, I do not mean that they should be manual labourers: but what I counsel is, that an educated man should guide and control the peasant, in his crude ways of obtaining a produce. There is not the slightest doubt, that with the exception of copperah, all other articles of produce have deteriorated and lost their high price in the market. At one time the Rajah of Travancore and other Indian agents commissioned English merchants in Colombo to purchase Tobacco in Jaffna. And the competition was so hot, that large profits were realised by the agriculturists. But now there is no such demand, and the tobacco goes about begging in the market, while the general complaint is that the tobacco is inferior in quality, and that the curing is not properly attended to. Perhaps the seed, for want of attention, has deteriorated, and manure being at present costly, the agriculturists are penny wise and pound foolish. Here then is an opportunity for Young Jaffna with his intelligence to step in and improve the cultivation. Again, there is a failure of a handsome return of paddy, because there is no attention paid to the husbanding of water, and the ploughing of the soil to a greater depth, than the two or three inches which from time immemorial have been thought to be sufficient to feed the grain. And yet the fault, in the decrease of produce, is attributed to bad luck, and the influence of fate, but the fault dear Jaffna, is not in our stars, but in ourselves. There is a tide, in the affairs of agrienlture, which taken at the flood, leads on to fortune, omitted, all the profit of the cultivation is blight and loss. The transplanting of plants, the importation of fresh seed-corn, the regulation of sowing and reaping, observing the changes of rainfall are matters which should well engage the attention of Young Jaffna. The farming of sheep for the purpose of exporting them to Colombo and other stations, is unquestionably a profitable employment. The soil of Jaffna, so full of saline matter with its low shrub-like grass, seems to be peculiarly adapted to fatten sheep, and yet we are told that sheep farming is not at all profitable because sometimes a large number of them die without rhyme or reason. I have taken the trouble of visiting the Islands to see the manner in which the sheep are attended to. There is no care whatever bestowed to procure them clean, and clear water in case of drought, and the sheep fold is simply a square, enclosed by a few brambles, and a few Palmyra leaves as an apology for a roof, while dung and other filth are permitted to accumulate, when an occasional shower makes the floor a mass of liquid filth. To me it is a wonder that sheep should withstand and survive such treatment. A man who takes to sheep farming in one of our Islands, combining with it the cultivation of tobacco and dry grain, with a small plantation of coconut, on the better soil, if he cannot make a fortune, will yet procure a competency of living and prepare the way for others to obtain a profitable livelihood.—*Cor.* "Ceylon Patriot."

PREPARATION OF TEA: FINAL FIRING.

Every year the value of a mark is becoming better known, and in a few years a large portion of Indian Tea will be sold without sampling. That it will take a long time to establish perfect confidence we are aware; but, once established, we do not thiuk that any doubt can exist in any one's mind that the advantage will be great on both sides. Commensurate advantages will, however, necessitate commensurate care in bulking and general manipulation of the crop; and great would be the fall in values to any mark which showed deterioration in quality. Within the last few years great changes have taken place, and year by year the advertising columns of all tea papers show that an entirely new and apparently remunerative trade has sprung up in manufacturing tea machinery. Several firms now make it a speciality, and when we say this is done, it means that a better article is being turned out at a lesser price than formerly. It would be invidious on our part were we to refer to any particulars on this subject, and planters are no doubt quite as capable as we are to speak practically on the subject of which particular machine is the best for its own individual branch. The fact, however, of a firm of the standing of Messrs Marshall & Sons thinking it worth their while to take up the manufacture of tea machinery is a guarantee that whatever the merits of the particular machine produced, the workmanship will be good. What we wish to point out particularly just now is the great risk which attends the introduction of any new machine for drying purposes. Of all the operations which conduces to give a good name to a mark, we consider that the proper final curing or "pucca *batty*" is perhaps the most important, and unless this is properly attended to, although all the rest may have been done quite correctly so as to insure a good tea, if the "pucca batty" is not properly given, all the planter's care and anxiety is lost. We hold the opinion that very few of the drying machines can affect a proper curing in the time they advertise, simply from the fact that sufficient time has not been allowed to drive off the moisture Another thing we contend is, that, instead of any hard-and-fast rule, as is often sent with instructions for *Dryers*, a great deal must depend upon the state of humidity of the atmosphere on particular days. After a long spell of drought, when the atmosphere is perfectly dry, we consider a shorter time would suffice for curing than on a wet day or after a continuous spell of wet weather. It is almost needless for us to mention that in old days "pucca batty" occupied 10 to 12 hours, whereas now-a-days we are informed that 20 minutes suffice. In the days of 10 and 12 hour pucca batty, no complaints were heard of soft teas or teas "going off," and we are inclined to put it down, at any rate in some measure, to the thorough final curing of the tea. It is useless to except if there is the slightest moisture left in the tea that it will go off in the chest, however warm it may be put into the box, for there is not, or rather ought not to be, the smallest opening for it to escape, if the soldering has been properly done. To final firing then all should look carefully, if they wish good results. Now that the quantity of Indian tea to be handled in London is so large, greater attention is required than formerly, as it no doubt necessitates greater exposure in London, and this will continue until "bulking" is recognised as a sufficient guarantee for a mark. We have heard of tea lying about in the warehouse at home for days, and no doubt deteriorating in value, and until remedied, we must on our part do all we can to assist in preventing this doing as little harm as possible.—*Planters' Gazette.* [We suspect that in most cases, it is not that moisture is left in the tea, but that there is over-firing. —Ed].

THE POLICY OF FOREST RESERVES IN CEYLON (AND THE STRAITS).

Under this heading Mr. D. Mackay writes as follows to the local "Times":—

When I left the island in the beginning of October last, the Government had just declared their decision to suspend all sales of land until the reservation recommended by Mr. Vincent could be settled, and an ordinance passed to carry out the new departure or policy (if such a term can be applied to what is simply a strangling of the only real life of the country), and on my return I find that not only has no ordinance been passed, but that practically the whole of the available and suitable-for-tea-planting waste lands have been closed against the enterprize of the planter, as if it were one of those evils to be specially guarded against and fenced off in the interests of the country and the general community.

To illustrate the evil that this insane and dog-in-the-manger policy is doing, I need only mention the circumstance of a gentleman from Assam having called on me (the day after I landed) to ascertain where he could get land in the lowcountry for tea planting, and my being obliged to tell him (with, I must confess, a feeling of shame for our Government) that no land was at present obtainable, except what might be in private hands, and so far as my knowledge extended I could not recommend him the latter, if he wished to go in for the best land for his purpose.

Enquiry at the Surveyor-General's office elicited the fact that not more than a thousand acres are now ready to be put up for sale, and though these few acres are in a promising district and probably suitable, yet I felt it my

duty to tell the man who had sought my advice that, if he had better not rely on any Crown land, as, from recent experience, it was ten to one that it would be withdrawn from sale even at the last moment.

Such a do-nothing policy is at the present time simply ruinous to the general interests of the country, and I am astonished that the recent Planters' Association meeting should have so utterly overlooked so seriously important a question, for I consider its speedy settlement of far more consequence to the progress and prosperity of the island than the disposal of any of the measures which they criticized and condemned on that day. The necessity of increased taxation and the principle to be applied in paying for reproductive works are no doubt in themselves questions demanding expression of public opinion, but they are of little importance when compared with the policy which shuts out the capitalists, and stops the way which lies so evidently open for a restoration at no distant date to our former prosperous condition; at the very time when, owing to the good prospects of Ceylon tea, both in quantity and quality, and probably to the uncertainty of China being again such a factor in the field, capitalists from India and home are seeking to invest in our lands, the Government shut them up; and the result will be that, as we cannot avail ourselves at the turning of the tide, the capital will go elsewhere and benefit other countries, and we shall have to dribble along till a change of Government brings us an administration which will look more to the development of the country, and particularly of its rising and most promising industry, than to carrying out crotchets which are not only false in themselves, but are ruinous in their tendencies. * * *

Every day's delay in the settlement of the question of the disposal of the waste lands suitable for tea growing means not only hindering the development of the tea enterprise, but disgusting, and driving capitalists and planters to other countries having stores of unused wealth in waste forest lands. If the Government stick to the present policy of locking up the whole (for it is practically so) of the low lands of the islands on the erroneous supposition that they are preserving from diminution the rainfall of the country, then the different Associations representing public opinion must, if they wish to secure for Ceylon the benefit of being next to India the largest exporter of tea to the London market, take immediate action and address the Secretary of State to have the present policy reversed; and, if it be necessary to effect that, let them demand a change of Government and a rule of common sense and not of crotchets which, however, pleasant to the mind that has devised them, are matters of life and death to the future of the colony, affecting all alike, both European and Native, and preventing advantage being taken of the long-looked for return of confidence in the future of the island.

The theory (for it is nothing else) on which the Government rest their defence of their present policy of obstruction to the development of tea planting, viz., the conservation of the rainfall (not of the forests) is utterly untenable and would be ridiculous were not such grave issues attendant on it. I could understand such a reason being advanced for such action were Ceylon situated in Central India with the sea a thousand miles away, but situated as it is in the very teeth of both monsoons and the sea breezes sweeping over it from side to side, it does not surely need even the experience of long residence to tell one that the rainfall can in no way be affected by the denudation of the forests, especially in the lowcountry. The rain clouds will be attracted by the highest hills, whether there be any forest in the intervening country or not, but there might be some need in reserving the highest ranges and sources of streams. I know of places within the so-called reserve to which it would be a godsend if the rainfall were diminished, but where I know it never will diminish unless the hills can be flattened down a bit. Were the reserve made and sustained in order to plant and grow timber for public purposes generally (for there is no timber within it worth conserving), there would be more sense in such a theory than the one put forward in defence of obstructiveness; but there is enough land and to spare to gratify both Mr. Vincent's crotchets in that line and give employment to the capital that is now seeking investment within the reserve, for it will not be turned off to utilize abandoned coffee lands so long as there is better forest land available. It is no new explanation of the real motives for locking up the Crown lands that the Government hope this policy may induce the utilization of abandoned estates, but unfortunately it is not new to know that capital will not be driven, though it may, if judiciously worked, be led into a new channel, even in what was in danger of being considered a worn-out country.

What we want now, and at once, is not a Forest Ordinance, but the appointment of a special officer of lengthened experience with a proper surveying staff, and full powers to settle what lands shall be reserved and what shall be surveyed and sold, exactly as was done with the chena lands, and which led to all the present lowcountry enterprize in tea planting. Such appointment should in no way be dependent on the Forests Ordinance, but rather should the latter be dependent on the results of the special officer's work—in fact, a Forests Ordinance made up after the reserved lands had been defined, would be much more likely to stand the test of time than one put together now with such a chaotic jumbled-up basis to work upon. With regard to the special officer for this work, all eyes will turn to Mr. Stoddart as the man above all others who would deal with the question as it requires to be dealt with, viz., quickly and finally, and who would command the confidence of all, both governing and governed, in the settlement of this most important and most vitally interesting question. There is no time to be lost; the hour has come, and the man is ready. We should ask the Government to make the appointment, and arrange to put up from time to time such lands as the special officer may select for sale. If this is done, capital will be encouraged from both India and home, and the development of the tea enterprize will progess with rapid strides, instead of langnishing, as it does now and going on at the present depressing and distressing snail's pace.

Taking the reserve and examining it even so far as known to me personally, the groundlessness of the alarm regarding rainfall, and the needlessness of the reservation will be at once apparent, for there is more than enough of land to satisfy legitimate demands and gratify all the whims of the forester and administrator. To begin at Hanwella and making on the south as far as the Kaluganga and Bope road the western boundary of the lands suited for tea, and on the north as far as the railway the road *viâ* Weke the western boundry on that side, there are all the lands to be settled enclosed within those lines, west, north, south; and another line from the railway incline, across by lower Doloshage and Yakdessa to the Peak, and thence to the Kaluganga at Ratnapura, an area of at least 800 square miles, or say 512,000 acres of land, of which at least one-fourth, including the land already taken up, would be suitable for tea growing. Say another fourth is left to gratify the cheuaing propensities of the natives, and the one-half of the land would still be left to satisfy the crotchets respecting rainfall and allay any fears there may be of our loosing some of our excessive moisture. Taking only the portion lying between the Kelani river on the north and the Kaluganga on the south, the road before-mentioned on the west, and up to the Peak on the east, and you find at least an area of 450 square miles or 288,000 acres, out of which there are not yet 10,000 acres taken out for tea cultivation, simply becau e it could not be got, and surveys were put aside to satisfy the fancies of a man whose only interest was to make a name for himself in connection with forestry.

Then with regard to the extensive tract south of the Kaluganga from the Kalutara estates on the west, to Rakwana on the east, and south to the Morowak Korale and Udagama, there is no less than 1,000 square miles within which the soil, rainfall and climate are suitable for tea-growing, and out of that very large extent no more than 1,000 acres is ready to be advertised for sale. This proportion or disproportion would be simply ridiculous were it not so serious. Here, as in the tract north of the Kaluganga, there is enough land and to spare to satisfy all purposes, whether practical or theoretical, and hence the wonder and the regret that the survey and the sale of lands suitable for tea should be suspended. It would appear that the interests of the tea enterprize are to

be made subservient to the recommendations of a gentleman whose sole object was to make a forest and who did not care two straws whether he stopped progress or not by so doing; and to the fears and fancies of a Government which apparently cares as little for the future prosperity of the country as Mr. Vincent, if they can but carry out their own rain theories which they forget are opposed to all the facts and experience of the last quarter of a century in connection with forest felling and land clearing.

QUEENSLAND SUGAR INDUSTRY AND THE LABOUR QUESTION.

SUGAR CRUSHING AND BOILING.

A sugar district, when crushing is in full swing, presents a most animated scene. The country roads are filled with great drays, whose sides are built up several feet, forming a hold for the cane which is thrown into them. In the brakes the Kanakas are busy with the knife, row after row of cane quickly falling to the ground, and as quickly being heaped in the drays. Men and women are hard at work. There are Tanna boys, finely-formed fellows, strong and healthy; Manicolo boys, equally good; and Solomon boys, with broad good-natured faces; while here and there a timid, fearful-looking fellow, with thin, scraggy limbs, represents the few survivors of the unfortunate New Ireland immigrants. The "boys" are clad or unclad, according to their own sweet will. Many are naked but for a loincloth, whilst others have the full rig of moles and shirt, plus billycock hat, generally abundantly adorned with cocks' feathers. Some of the islanders have their ear lobes cut and elongated in a most extraordinary manner, so that a loop is formed, the lower extremity of which almost dangles against the shoulder. The ears of others are simply pierced, and pieces of stick inserted in the orifices. When a dray is laden with cane it is taken to the mill. The mill is usually situated in the centre of a great open square. The hum of the machinery is heard in the distance, and when over the green waving tops of the cane brakes on either side the building comes in sight, one sees the boys scattered about the great square raking the megass or carrying great bundles of cane from the drays to the endless traveller that feeds the mill. There are generally a large number of men and women at this work. The women are clad in cotton skirts, and have generally a bright-coloured handkerchief bound round their heads. The whole picture, in fact is full of colour. There is the background of green tops; then, in the foreground, piles of cane stripped of leaves, with their knotted stems, bright scarlet, rose-tinted, some with a bloom like that on the skin of a damson, others rich yellow like the skin of the ripe gage; then here and there a clump of bamboo, with long, graceful, leafy streamers floating on the breeze; then, beyond the river, with tangled tropical plants, out of whose massed luxuriance spring Alexandra palms, with their tasselled bunches of red seed; and beyond all, the distant purpled hills, and overhead the blue sunny sky, with here and there a white cloud that drifts lazily along, sometimes throwing its shadow on the fields and sometimes on the river. But the mill has no thought of all this. It is decidedly practical, and it hums and crushes and whirls ceaselessly. Here comes a Kanaka girl with a great bundle of cane; down it is thrown on the travelling way, and in a minute it has reached the close-set rollers that are to crush it to pieces. Under they go, and the bright scarlet canes come out at the other side poor, mangled, torn strips, and the juice flows in a white, foamy stream into the trough below. The mangled fragments, which are technically termed megass, are taken away to be spread on the yard, there to dry, and afterwards be used as fuel; or if there be a double mill, it is carried on by the traveller to the second set of rollers, where it is crushed again, so that not a drop of juice may be lost. Now let us follow the white, creamy juice which we saw flowing from the grooved surface of the rollers. It pours along a trough into a sort of straining bed, where it is filtered through a plate pierced with holes, and accumulates in a well beneath, whence by pumping it is carried up a pipe till it reaches the top of the mill-building, and there it flows into a tank or tanks at the bottom of which are perforated pipes through which sulphur is injected into the juice. From these it is carried to a series of other tanks, known as clarifiers, where it is heated by steam pipes and where lime is thrown into it. A thick yellow scum rising to the top is skimmed off and, except in a few mills where it is gathered and pressed, is thrown away as refuse. The lime has an effect upon the acid, and renders the juice almost neutral between acid and alkali. The juice, which has now become about the colour of old brown sherry, is carried off by pipes to the batteries, where it is boiled at a fierce heat, the effect being to bring it to a density of about 18° Beaumé. In a cloud of steam kanakas are keeping the liquor stirred up. The hot juice is then passed into another set of tanks known as subsiders, where it settles and the heavier substances that may not have been before extracted fall to the bottom. When it has settled sufficiently, it is carried by pipes into a sort of drum well, whence it is lifted by a pump to the vacuum pan. The object of the vacuum pan is to boil the juice at a low temperature in vacuo. At one time the boiling was done in Wetrzell's open pans, but an immense heat was required, and there was always the possibility of burning; and as burnt sugar is one of the most intense colouring mediums known, such a mishap was of serious consequence. In vacuo the boiling can be done without any such fear. The vacuum is generally created by means of an air-pump and engine, the vacuum obtained being about from 25 to 26 inches of mercury—the most perfect vacuum man can make is about 28½ inches of mercury. The boiling in vacuo is done at a temperature of from 118 to 150 degrees, whereas the temperature at which water boils in the open air is, I believe, 212 degrees. The sugar-boiler, who is a man of great importance at the mill, is skilled in knowing the exact time when to withdraw a panful of sugar. The vacuum pan is, in general appearance, like a huge kettle-drum, inverted on a low column, which it exactly fits. In the metal surface of this drum is fixed a glass disc, through which the sugar is seen boiling within; and, by a most simple and ingenious contrivance, a tester can be inserted and a sample withdrawn to see how the sugar may be granulating. When boiled sufficiently the juice is discharged into coolers, each holding a charge. These coolers, in the greater number of cases, travel upon rails, so that their contents can be removed, and, when cool, discharged conveniently into the pug mills. In the pug mills the juice, which has now become of a thick consistency and granulated, is poured, as it may be required, into self-adjusting centrifugals, which are generally situated immediately beneath the pug mills. The centrifugal in general appearance represents an inverted mushroom, the stalk being a heavy steel rod, and the head a sort of basket, constructed of wire gauze. When the basket is charged with the thick juice the shaft is rapidly revolved, and by this action the juice is forced outward against the gauze, the crystals or grains being unable to escape are caught against the gauze screen, but the molasses is forced through the holes, and becomes thoroughly separated from the granular particles. The mill is then stopped, and a man with a small wooden instrument scrapes the sugar from the basket of the centrifugal, and the contents are emptied into travelling boxes, and thence taken to the sugar warehouse, where they are screened and bagged. The sugar from the juice the first time it is passed through the mill is known as "firsts," or "first counter." The "seconds," "second counter," is the sugar extracted from the molasses which is separated in the centrifugal mills from the "firsts." In making seconds the molasses takes the place of the juice direct from the cane, and goes through exactly the same process, with the exception of the sulphur injection. Sugars are made down to "fourths," which represent the lowest class of ration sugar. This brief description gives a general idea of the principles of sugar making, but in many cases the minutiæ of the process are varied. For example, in some instances steam is used for all heating and boiling purposes. The old-fashioned battery, heated by fire beneath, still exists in a few mills, but the more general plan adopted is that of heating by steam coils. Then, again, the sulphur-injection process is varied, and in some instances the liquor is limed cold instead of hot. Also, scum presses are used in some mills in order to extract the juice from the scum, which in the old days was, and in some cases still is, thrown away as useless. Aspinall pans are also used after the juice has passed

through the batteries. The juice is boiled in these pans at an intense heat, and the evaporation being great the density of the liquor is increased. In fact, each season some improvement is made in machinery, and competition is becoming so keen that each labour-saving idea represents a monetary interest to the fortunate inventor or adapter.

Last season it took about 1,620 gallons of juice to make a ton of sugar in the Mackay district, although it has been said that 1,500 gallons has yielded that amount; but this, to say the least, is a very questionable statement. In Demerara, where there is both the highest cultivation and the most perfect appliances, the average is 1,600 gallons to a ton of sugar. The weight of cane required this season to make a gallon of juice. is from 1,800 lb. to 1,900 lb.

Mr. Ling Roth, late secretary to the Planters' Association of Mackay, gives the following comparative table of yields per acre in various sugar-producing countries:—

Country.	Average yield per acre.
Demerara	4,480 lb. of sugar.
Louisiana	1,200 lb.
Mauritius	3,500 lb. to 5,500 lb.
Jamaica	1,344 lb.
Philippine Islands	2,800 lb.
India	896 lb.
Rio Janeiro (Quissima) ...	2,800 lb.
Java (about)	3,360 lb.
Queensland	2,884 lb. (1 ton 5 cwt. 3 qr.)

From this it will be seen that Queensland cane holds very good place among that of other sugar-growing countries. From July 1 to December 31, 1883, the export of sugar from Queensland was 16,435 tons.

About five miles distant from Mackay, on the Nebo road, is the Te Kowai estate, one of the poineer plantation of the district, and portion of the property of the Melbourne and Mackay Sugar Company. This company owns the following estates in the Mackay district besides the one mentioned:—The Palms, about 1,700 acres in area; Alexandra, about 2,500 acres in area; Peri, about 1,400 acres in area; Branscombe, about 1,430 acres in area; and Nebia, about 1,030 acres in area. These two latter estates are worked as one. Of course these areas do not represent the cane land under cultivation, but only the total extent of land in each estate. At the time of my visit to Te Kowai the mill had just commenced crushing, and the cane drays were bringing in the produce. All was bustle. Here, a group of kanakas spreading out the megass or carrying it to the furnaces for fuel; there, a string of boys and "marys" carrying bundles of cane to the mill, where the huge rollers made the cane crackle and crunch like the sound of a discharge of fireworks. Kanakas, stripped to the waist and in the midst of a cloud of vapour were stirring up the boiling juice in the batteries with long handled pans. White men were busy testing the density of the juice, and engaged in all the necessary skilled work of a large sugar-mill in the crushing season. The area of the Te Kowai plantation is 1,574 acres, of which 1,059 acres are under cane this year. In addition to the mill there is a rum distillery. Rum distilleries, from what I have seen of them, appear to distil anything that comes in their way. The material they get to work on is the refuse molasses out of which no more sugar can be obtained, added to this are the sweepings generally. Last year the output from the mill was 760 tons of sugar; but it was a very bad season, principally by reason of the want of labour to keep the weeds under. The crop this year, however, looks better. There are 200 kanakas and about 50 white men employed on the plantation. The kanakas, of course, receive the regulation wage of £6 a year, with rations, clothing, housing, &c. This refers to what are called by their brethren "new chums." Re-engaged kanakas get about 10s. a week with rations. Then as to white labour, ordinary hands—labourers—receive 20s. a week, ploughmen 25s. a week; mill hands, such as engineers, from £10 to £13 a month, with double rations, ordinary rations being given in every case. Sugar-boilers receive £10, blacksmiths £8, and cooks the same per month. The cost of a white man's rations per week is estimated at 10s., and that of the kanakas about half the sum, not including in either case the interest on outlay in houses, &c.

"The Palms," which was established in 1881, is one of the estates of the Melbourne and Mackay Sugar Company. It comprises about 1,700 acres of land, of which area about 1,500 acres are this year under cane. This represents a little larger area than was under crop last year. "The Palms" is noticeable principally for its excellent plant of machinery. Some idea of the amount of money invested in sugar plantations may be gained from the fact that this plant alone at "The Palms," and that not including the building, which itself cost about £9,000, is valued at about £24,000. The machinery generally is from the house of Mirrless, Tait, and Watson, of Glasgow. The principle is that of steam concentration, nothing whatever being boiled over the fires. Previous to the erection of the new plant, the common lime process was used, and half of last year that known as Icery, Erhman, and Bernhardt's was worked. Under this latter process, it is calculated that about 90 per cent of the whole product can be turned out in "whites," although this is done at a certain loss in quantity. Nearly the whole of the competition in the Mackay district is in the production of white sugars, rations being quite a secondary consideration. To work the plant there are four boilers, each of 100 horse power. The boiler house is separated from the main building, the steam generated being carried across in pipes. The main building, which is a very substantial framework covered with galvanised iron, is about 179 feet in length by about 84 in width. The machinery has that bright cleanly appearance which shows care and attention, and is so disposed in the building that the engineer has under his eye all the plant directly connected with his department, and the same is the case with regard to the sugar boilers. There are six centrifugal mills, each making 1,200 revolutions in the minute. An average day's work at this mill would be represented by an output of about 15 tons of sugar, though, as a matter of fact, 20 tons a day have at exceptional times been put through. In connection with the plantation there are a number of outbuildings, such as the residence of the manager, Mr. R. E. Donaldson, the houses of the white and coloured labourers, a stable for 72 horses, with two outstations for 15 horses each, blacksmith's shop, and so on. There are 150 kanakas, and a number of Malays and Sinhalese, making the total of coloured labour employed on the plantation 185; but the full staff of black labour should be 240. Then there is a regular staff of about 70 whites engaged as sugar-boilers, engineers, &c. The wages paid to the whites on this plantation amount to about £370 a month, and those to the coloured men £250 a month. Rations are provided in each case, in addition. From the above figures it will be seen that the large sum of £4,410 is annually paid in wages to white men consequent—so the planters put it—upon the labour represented by the £3,000 paid in wages for kanakas, &c., without whom, it is said, it would be impossible to carry on. This sum of £7,440 is strictly payable to wages, but in addition there are other expenses which may be calculated at quite another thousand pounds per annum, so that altogether about £9,000 represents the annual expenditure of the plantation, not calculating interest on capital, and outlay in connecton with the business, but not strictly chargeable to the mill or plantation and so on. Then, with reference to white *versus* black labour, he remarked:—"I maintain that at canework a kanaka will use the knife all the day through where a white man could not do so."

The Pleystowe plantation, the property of a Melbourne syndicate, is distant about 11 miles from Mackay, on the southern side of the Pioneer river. It comprises an area of about 5,000 acres, of which 700 acres are at present under cane, and 200 acres of cane will be purchased for the mill from neighbours. It is one of the oldest estates in the district, and certainly one of the most beautiful.

The Manager, Mr. Steadman, said:—"We employ 153 kanakas and 40 white men. The average on the plantations in this district is about one white man to four kanakas. "About 15 months ago two shiploads of white immigrants came to Mackay, and as they did not go off very well the immigration agent asked some of us to take a few, and several of use did so. We took them at 15s. per week a-head, with rations and lodging, of course. My experience of them was that they could not stand the work. It was both the climate and the kind of work. There were some men who had been in the country three or four years, who were getting 25s. a week doing work for us, and

they told the new chums that they were fools to work for 15s a week. Often I take new chum ploughmen on here, hiring him in town at 20s. a week. Well, new chum ploughmen are not very good, they do not understand the country or the way we have here, and consequently it takes them really a year or two to get into the way of doing work in the colony; but they are no longer here than two or three weeks than they ask for more wages, put up to it by the others, and of course we have to discharge them. A new chum labourer is of very little use until he has been here about from 15 to 18 months."

I have been in India and on a coffee plantation, and I am thoroughly convinced that if we got the proper class of coolies from India—that is to say, the agricultural class—they would do nearly as well as the kanakas, and I do not ask for anything more. I prefer the kanakas all round, but still I would be satisfied to have coolies. I do not think there would be any probability of coolie labour entering into competition with white labour. We would get the agricultural class, and their traditions from time immemorial has been to keep to one trade, namely, that of an agriculturist. In India a man is a carpenter all his life, and his children after him are carpenters, and so on in every kind of trade. Harm has been done by bringing to the colony a number of Sinhalese, who were simply loafers about town, and were of all trades and professions. These men have certainly done a great deal of harm, because they have tried to compete against white men. But these are not the men we want at all. We wish to have Tamils, and also Canarese from Mysore, but especially the latter. The kanaka boys make excellent horse-drivers. They take great care of the horses and become very fond of them. It is considered a promotion for a boy to be given the care of a horse. My orders on the plantation are that no one shall touch a boy. Should a boy misbehave himself he is reported to me, and I deal with the matter. I have dismissed men for disobeying this order.

The Marion Mill is distant about 18 miles from Mackay. It is the property of the Mackay Sugar Company, and is the only mill worked on the purely central system in the district. The manager of the mill is Mr. A. R. Mackenzie, who is in enthusiastic sugar man; indeed, his whole existence appears to be merged in the determination to turn out the best "first white" in the district. The Marion estate, consisting of about 2,000 acres, was purchased by the present proprietary from Mr. John Walker, of Homebush, and the purchasers then proceeded to cut it up into farms of from 60 acres in extent upwards, and these farms were sold at the rate of £6 per acre; £1 per acre was paid cash down, and instalments of £2 14s. per acre, bearing interest at 8 per cent were payable at each of the two crushings after the first one, these sums being deducted from the cane money. The principal condition of purchase in these cases was that the purchasers should supply the mill with cane for seven years, the price at present given being 10s. per ton for cane as it stands in the field, the millowners doing the cutting and carting, or 13s. per ton if the farmers deliver the cane at the crusher. In cutting the estate into farms two reserves were left, one for the mill site and another of 469 acres, in order to supply the mill with cane should that ever be found necessary beyond the farmers' supply. This area has, however, since been leased on eight years' tenure at a nominal rental, the mill agreeing to crush the cane grown on it up to certain quantities, and, if possible, the whole of it.

In the course of conversation with Mr. Mackenzie, he remarked:—I have found kanaka labour very satisfactory so far; the boys are docile, obedient, contented, and thoroughly reliable. We never have any trouble with them, and very little sickness among them. We have only lost one boy—and that was by consumption—since we started, and that death was in the hospital. I do not think that white labour could at present prices be possibly substituted for kanaka labour. If black labour were taken from us the mill would have to be shut up. Kanakas make invaluable horse-drivers. They never ill-use the horses, but become attached to them. I have known a boy to cry because his horse was taken from him to be given to someone else. Of course there is a white man in charge of the stables. I really do not think that white men would do the work, or if they could, we could not afford, at the present price of sugar, to pay them what they would require. There is not one of the farmers attached to the estate today who could do without black labour. Coolie labour would do us. I have been seven years among coolies in India. The agricultural coolie in India is very different from the few Sinhalese who were imported to Mackay, and who proved a great failure. In Ceylon there are a number of coffee plantations, and they are worked entirely by Indian coolies, and never by Sinhalese. The word 'coolie' means wages, and a coolie is a wages man. I believe they would do very well here, though I do not say they would be better than the kanakas. I do not believe the coolie would enter into competition outside of the cane-field with the white man. In India trades are all regulated by castes. If a man be born of the carpenter caste he will never become an agriculturist, or *vice versa*. He could not do so. In the first place, his own prejudice would prevent him, and in the second his fellow workmen would stop him. Beside this, the work done by the Indian carpenters and artisans is of such a rough description that the Englishman would have nothing to fear from it. In the 'Indian Coolie Act' it could easily be arranged that only agriculturists would be eligible, artisans could be made ineligible, as coal-miners are under the Queensland White Immigration Act. The cost of a kanaka for the time he is in Queensland would be about £25 in cash to get him, then £18 in wages for the three years, and beside these, rations and clothing, housing, &c., and then there is always certain proportion of sick ones, whose wages have to be paid the whole time of their sickness, and these, together with those who die and those who are inferior labourers, would make it a considerably large sum per head. If the kanaka trade were abolished, the white man certainly would not benefit by it, because a vast number who are now employed consequent on kanaka labour being available, would be thrown out of employment. No wages are paid on this estate to white men under 25s. per week, and some receive as much as £2 10s. and £3 per week, with rations and housing in all cases.—*Sydney Mail*.

AGRICULTURE IN COORG, SOUTHERN INDIA.

(*Report on the Administration of Coorg, for the year 1883-84.*)

From the Report we quote as follows:—

Agriculture.—The extent of land under food grains remained stationary. 73,021 acres are shown as cultivated with rice, and 1,433 acres with dry crops or 6 acres less than in the previous year. The most important industry in the Province is that of coffee planting. There are altogether 218 coffee estates owned by Europeans and 4,428 by Natives, comprising a total area of 74,074 acres. The area of the land held by the former is 38,213 acres on an assessment of R69,398, and by the latter 35,861 acres on an assessment of R65,892. Much coffee is also grown on the bâines (uplands attached to rice fields), the extent of which is roughly estimated at 13,000 acres. The average size of each coffee plantation held by Europeans is 185 acres and by Natives 8 acres. The number of persons resident on European coffee estates and large Native estates is 26,893, according to the last census, which was taken on the 17th February 1881, but this number is augmented by about 20,000 during the picking season which closes in January. Of the whole area of land under coffee cultivation 41,600 acres are said to be in full bearing. Owing to the heavy crop picked, the outturn, estimated at 2 cwt. the acre on Native and 4 cwt. on European estates, came to about 5,109 tons, being nearly double the yield of the previous year. Taking the average cost of cultivation at R100 per acre on European estates and R40 on Native, each cwt. of coffee costs on an average R23 to produce. The cost of cultivation at the rates per acre assumed above comes to nearly 29 lakhs of rupees. Of this not less than 60 per cent may be estimated as having been paid to laborers as wages. The value of coffee produced, taking the selling price to be on the average R25 per cwt. on the spot, came to R25,54,500. It would have been R5,10,900 more had the prices of previous years been maintained.

Labor.—For the first time for several years past, the planters experienced great difficulty in procuring a sufficiency of labor for plantation work. The Mysore coolies were late in coming in, and, when the batches did arrive, they were less than half the number for whom advances had

been made. The causes assigned were the abundance of the crops which had caused a fall in prices of food grains, and the demand for labor on the Bangalore-Tumkur Line of Railway, which was under construction. Some of the estates suffered from the weeds not having been removed in time, while in other cases the managers and proprietors were saved from heavy loss only by the strenuous efforts, which they made to import labor from the Tamil country near Salem, and by employing the costly but valuable labor from the Western Coast. Owing probably to questions affecting the tenures of land in Malabar, the numbers of coolies, chiefly Moplas who were attracted from that part of the country, were unusually large; and with their aid the difficulty of securing the crop was tided over. Many of the Tamil coolies, who were imported, failed to give satisfaction, but others have done well, and their advent to the country is welcomed, the more so as many of them are willing to engage without advances. The Mopla laborers proved also most useful in doing good work on petty contract on the roads. The alarm which arose in the minds of the planters from the unforeseen difficulty about labor as above described, has passed away, but not without attracting attention to the necessity of labor being drawn from more than one source of supply, and to the advantages which would result to the community by the construction of a Railway, which would facilitate communications with distant parts of the country.

Price.—No greater blow has been dealt for many years past to the prosperity of Coorg, and to the coffee interest, to which it owes its flourishing condition, than the heavy fall in the market price, which took place at the close of the season. It has decreased from R40 to R25 the cwt. within the last two years, and in the Home market from 100 shillings to 61 shillings, or 40 per cent. The cause is attributable to the overstocked condition of the London market. The *Times* in a recent issue describes the stock as apparently inexhaustible, and states that it is not known to how low prices may still fall. Ceylon and Coorg have to compete with Brazil where there is slave labor, and where fresh land is said to be abundant. The extension of Railway communications in Brazil is another advantage in favor of that country, and in recent years the planters there have been taught by settlers from Ceylon the proper manner of curing and preparing coffee, so that Brazil coffee has lately obtained in the Home market as good a price as that of Coorg. The native coffee is chiefly in request for the French market, to which quantities have been exported direct from the Western Coast. Owing to the good crops reaped in Mysore, the prices of food grains showed a tendency to fall still lower. Rice, the staple crop of Coorg, fell to R1-12-0 the maund of 80 lb. or annas 12 less than in the previous year, and ragi to R1-2-0 or annas 5 less. The market was so dull at the end of the harvest in the Yelsavirshiune Taluk, that sales could not be effected for some time. The ryots acknowledged the liberality of Government in giving them time to effect a sale by the recent alteration in the payment of instalments of revenue.

Weather and Crops.—The rainfall during the year was slightly above the average:—

		In.	cts.
That registered in	Mercara being... ...	140	29
,,	in South Coorg	80	35
,,	in East Coorg	44	33
,, and on	the Western Ghats ...	252	79

The season opened very favourably for all agricultural operations. The timely blossom showers led to fine crops of coffee and cardamoms being picked. The subsequent rains ensured the safety of the rice crop, which was fully up to the average: but in Eastern Coorg serious damage was done by the heavy rains to the ragi and Bengal-gram crops, especially by two unexpected downpours, which took place in the month of December. These showers caused also some damage to the coffee crop when drying on the barbacues, and to the rice crop in South Coorg.

Cinchona.—Consequent on the poor returns on many estates from coffee, greater attention is being paid by planters to cinchona. A number of plants have been put down among the coffee trees, and in a few cases separate plantations are being found on lands, originally taken up for coffee. The returns give 1,494,385 plants covering an area roughly estimated at 1,868 acres, or 782 in excess of that planted out during the previous year. It is found to succeed well both when planted in the open and with shade; but, as might be expected, does not do so well in exhausted soil, and as it is a surface feeding tree it has been found to be detrimental to coffee, when planted with it. The variety known as *C. Succirubra* appears to be the hardiest. The returns show that 855,423 plants consist of this variety; while of the other varieties, *Ledgeriana* numbers now 82,612, and *Calisaya* 71,000. The Reverend G. Richter has found by experience on his estate that the new process of bark shaving causes deterioration on repetition in the quality of the bark, and renders the trees liable to disease and early death. While bark from the first shaving sold in 1882 at 3 shillings and 8 pence, bark of the second shaving from the same tree fetched 2 shillings 4 pence only per lb. Many of the trees, twelve to fifteen years old, dried up after the second shaving.

The few Ceara *rubber* trees put down for experiment are growing rapidly to a great height. The oilpalm (*Elais Guineense*) has flowered, and a Carob tree on the Polibetta estate came also into full blossom.

Tea has been found to grow readily in Coorg, and as it is a hardier plant than coffee it is thought possible that it may take its place. Its cultivation has not yet been attempted, as the heavy rains in the monsoon and the heat and drought in the spring of the year are considered ill-adapted to cause the numerous flushes that are required. On the Sampaji Ghat it might, however, receive the aid of artificial irrigation from the numerous running streams, which are met with on most of the estates.

Horticulture.—The coffee enterprise is at present passing through the most critical stage in its existence. But while in other parts of Coorg its cultivation has been more or less a failure resulting in heavy loss of capital, the good management, judicious expenditure, and well directed efforts of planters, based upon the experience gained in the past, have resulted in securing most satisfactory results in that recently-opened tract of country in South Coorg, known as the "Bamboo." There and on the Suntikoppa side of the Mercara plateau are to be seen fine sheets of coffee extending for miles together. The secret of success has consisted in the early propagation of suitable shade trees as a protection against the numerous enemies of the plant, and in the pursuance from the commencement of a system of high cultivation. With the fine crop which was picked, the largest yet known, it was confidently expected that the labor given and the outlay incurred would at length be repaid by handsome profits; but the result has been only a disappointment; for the heavy fall of 40 per cent in the price of the berry has upset all calculations, leaving little or no margin for profit. The result is that Banks and agents refuse to make advances on the crop, and that estates are generally unsaleable. This is a great discouragement to the European gentlemen, fully 200 in number, who have taken to the cultivation of coffee in Coorg as a means of livelihood, and also to the numerous Natives who have been induced to embark in the enterprise, and who often, from no fault of their own, now find themselves in very embarrassed circumstances. These remarks apply immediately to that part of the country, known as the "Bamboo," and to the fine estates of Messrs. Mangles and Macpherson on the Suntikoppa side; but there are other portions of Coorg in which climatic and other reasons have led to the abandonment of estates and to heavy loss of capital. As large remissions of revenue to the extent of R23,335-0-10 yearly have had to be sanctioned in consequence, the following extract taken from a special report submitted lately on the subject by the Commissioner is quoted, as affording further information of the circumstances which have led to such detrimental results:—"The cultivation of coffee which was introduced into Coorg in 1835 by Major LeHardy, the first Superintendent, was confined at first to the two estates on the Mercara plateau, known as "Beuvoir" and the "Mercara estate," and to a few holdings owned by Mopla settlers near Nalknad in the Padinalknad Taluk. In 1858 land was opened on the Periyambadi ghat, and in 1863 a great stimulus was given to the enterprise by the rise in the price of coffee, when clearings were first made at Madenad on the Sampaji Ghat. Unfortunately some of the first settlers who came from Ceylon set the pernicious example, which was followed by all planters for the first fifteen years, of clearing and burning the forest

instead of adopting the safer but less remunerative method which is followed in Mysore of growing coffee under primeval or secondary shade. Other mistakes were made in land having been taken up for cultivation without regard to the excessive rainfall and the steepness of the hillsides. The forest, which crowned the mountain crests and covered the rocky spurs, was indiscriminately felled, so as to obtain a large open field for coffee, by which means the estates were deprived of valuable leaf manure and the greater portion of them became exposed to the full blast of the south-west monsoon, or the still more trying hot east winds. So long as labor was cheap and plentiful, the system of hand weeding, which caused little disturbance of soil, was followed; but as it grew dearer, the *mamoti* (native hoe) came generally into use for the removal of weeds, which grew rank and long from not being eradicated in time. It would not have mattered much, had the lands been comparatively flat as in the "Bamboo" and in the Wynaad where it is practised with advantage, but in a mountainous country with a heavy rainfall varying from 140 to 240 inches in the year, it loosened the surface soil so greatly as to lead to its being gradually washed away; and the trees thus became unable to assimilate nutriment, even when supplied to them in the form of expensive manures. The system pursued was not only faulty, but climatic influences and pests, over which the planters had no control, have greatly tended towards the deterioration of estates. The seasons have proved of late years most unfavorable, especially on the Sampaji Ghat, where the early blossom showers, which are expected in the end of March and in April, did not fall till May, which was too late to ensure the healthy development of the blossom and fructification of the berry during the monsoon. The coffee trees have suffered also from borer' (*xyletrechus quadrupes*) bug, (*Lecanum coffeæ*), and leaf rot, and lastly from the leaf disease (*hemileia vastatrix*) which has caused so much loss in Ceylon. It may be safely asserted that the pioneers, who obtained free on application large tracts of forests from Government and had the advantage of cheap labor, and the valuable compost arising from the burnt forest to aid cultivation, were the only persons who derived substantial profits; but it was only for the first few years, and chiefly from the high prices paid to them for the land by the companies which they succeeded in establishing. As profits decreased through mismanagement and the ravages caused by the borer, less funds were available for high cultivation, which became essentially needed, owing to the rapid deterioration of the soil. The result has been that all the companies were wound up withiu a few years, and many of the estates fell at almost nominal prices into the hands of the managers and agents, who, though experienced men, became thus possessed of much more land than they could well cultivate. Subsequently with adverse seasons the condition of the estates has been passing from bad to worse. The humus having been washed away, it seems only a question of time as to when their entire abandonment will take place. On many estates only long rows of weather-beaten sticks are to be seen, bearing a few shrivelled leaves with a few patches of good coffee still left in lowlying valleys and in sheltered nooks. Such being the case it is no ground for surprise that these properties have now no market value; for when put up to auction no bids are made for them. There are a few estates, which are not quite so bad as others, owing to good management and high cultivation; but it is doubtful whether any of the forest or ghat estates have of late years been worked at a profit sufficient to meet the interest on advances made by firms, any realized in one year, such as the last, being fully absorbed by the losses which have accrued in the years preceding or following. These statements are supported by the testimony of unanswerable facts. Between the year 1870 and 1880, 18,476 acres of coffee land were abandoned, and are now overgrown with lanthana; in 1881, 593 acres; in 1882, 2,156 acres; in the current year resignations have been received for 2,344 acres, making a grand total of 23,569 acres, which at R2 per acre (the assessment charged) represents an annual loss in revenue to Government of R47,138. The loss of capital to those who have invested in the enterprise cannot be so accurately stated, but it may be roughly estimated at £67,000. Although planters have become wiser after their dearly bought experience, it cannot be denied that errors were made by the authorities in the commencement by the free grant to them of too extensive tracts of forest land without any stipulations as to the reservations of belts of forest and the mode of culture. Government did not however remain wholly callous to the losses which were taking place; for, consideration was shown in the remission of the assessment due on portions of estates which had to be abandoned; while others received in exchange valuable land in the "Bamboo," by which they were enabled to recoup the losses which they had sustained on ghat land. The latter arrangement was, however, so obviously detrimental to the interests of Government and unfair to new-comers, that it had to be discontinued. Lately, the continued losses which the planters generally have suffered, and the sight of the deserted bungalows and lanthana covered estates, which meet the eye all along the Sampaji ghat, and in the greater part of the forest and the Mercara plateau, have necessitated the grant of still more liberal concessions in the way of remissions and suspensions of assessment, in the hope that proprietors and mortgagees, notwithstanding the difficulties which surround them, may be encouraged to undertake the cultivation of other products, such as cinchona, cardamoms, tea and rubber on lands which are unfit for coffee, and the abandonment of which has been frequently contemplated."

FUNGI AND DISEASES OF PLANTS.

(By T. J. Burrill, Illinois Industrial University.)

ORIGIN AND DEVELOPMENT OF FUNGI.

The idea is too common that such things as mould on moist bread, black velvety stains on the surface of Peaches, &c., may spontaneously occur through some combination of climatic effects, without the necessity of pre-existing germs of each particular kind; but these things no more arise in this manner than a young Peach tree starts from a ball of clay peculiarly mixed, or from the seed of an Oak. Each fungus produces its own seed-like bodies, "spores," and from these alone is their reproduction possible. One mildew does not change it into another one, and none are anywhere developed except as offspring of parents, as among the higher inhabitants of earth. Where, therefore, the germs of any particular parasitic fungus do not exist, no possible combination of circumstance or of things can cause such fungus to spring up into life and development. Were it not for the existence of the special kind of spores capable of germination, no amount of showery weather would make Wheat rust, nor fog and rain cause Grapes and Peaches and Apples to rot. Neither are these spores gifted with any powers of distribution beyond that afforded in the regular order of nature. They are carried by the wind, but cannot float in still air; gravitation as surely brings them to earth, save when carried by stronger forces, as it does cannon balls and meteorites. As we gain knowledge of the facts and processes of Nature, the powers of good or evil genii of the air diminish, and at last their existence is altogether denied. No one of intelligence now believes witches by acts of will blast the crops and curse the fields. The reign of universal law, affecting alike the minute and the great, the inorganic and the organic, the dead and the living, the nerveless and the sentient, is acknowledged and verified by the science of our day. Things do or do not take place, not according to chance or supernatural power, but according to the regular and orderly procession of natural law established and perpetuated by Him in whom there is no variableness nor shadow of turning. Every effect has its cause, and we ought never to think any of these causes are past finding out or beyond the comprehension of man. With the knowledge we now have concerning all, including the most obscure and minute species of living things, there can be no hesitation on the part of the informed in accepting the present existence of any fungus growth as positive proof of a pre-existence of its special germ, and of the development of that germ under sufficiently favourable conditions. Plant diseases occur as new in given localities, though the soil, climate, and cultivation of crops are as nearly as possible as they have been for many years. It is only recently that one the mildews on American Grapes appeared in Europe, though it is already widely spread on the continent and is the cause of much alarm. The

conditions of weather and of the Vine have for generations been as favourable for the growth of this mildew as they are now; only one element has been wanting—the spores. The latter have finally crossed the ocean, in some way carried by man, and now the rapid development proves the suitableness of the existing conditions for growth, but their inadequacy for original production. In the same way the black rot of American Grapes can be traced to infection from Europe, and the same lessons arrived at.

A few years since a parasitic fungus previously known in South America, gained introduction to southern Europe and gradually spread over the continent, carrying destruction to the Hollyhock as it went. Reaching England its ravages were especially marked, since considerable prominence is given this popular flowering plant. The Hollyhock is closely allied to the Cotton plant, and as these fungi sometimes grow on botanically related species there was cause for apprehension, lest the parasite should be again, transported across the Atlantic and bring serious trouble to our sisterhood of Southern States. The watery bearer was actually passed, but fortunately the Cotton did not prove susceptible to its withering effects.

The primitive origin of these species of fungi we will not discuss. They in some way, at some time, came into existence, and in the same manner that other species of living beings, not excluding man, were originally produced. Evolution has been studied, and in its light species are said to be transformations of previously existing species; but this does not in any practical sense affect the foregoing, because the process is reckoned by centuries and eons, not by years or the generations of men.

It is possible that change of habit sometimes occurs to such an extent that a fungus species not formerly capable of growing on a certain host species, becomes adapted to the latter; but nothing of this kind has been definitely observed. There is, however, the widest variation among the species of parasitic fungi as to the limits of their restriction to certain host plants. Many are found only on one species; very few (except such as have a peculiar alternation of habitat after the manner of many animal parasites) grow on plants belonging to different botanical families. Yet a few affect many species of flowering plants, even sometimes those of quite different orders. In the latter cases there is usually more or less difference in the vigour and appearance of the fungus on the different hosts; so that it is not easy to decide by form and appearance alone whether a certain parasite on a certain nourishing plant is, or is not, a distinct species, or only a modified condition of something known elsewhere. Artificial cultures, by transferring the spores from plant to plant and watching their development, are the only criteria when such doubts occur; and this is entirely feasible, though it requires much care and skill to secure reliable results. The so-called black rot of Grapes is caused by a minute fungus parasite of low and simple organization affecting the young stems and leaves (petioles and veins), as well as the fruit. There is also a disease of the canes and leaves (petioles and veins) of Black Cap Raspberries and Blackberries caused by a little fungus so similar in every way as seen under the microscope that one is inclined to pronounce them identical; but cultures prove them distinct—a point of considerable practical importance.

GERMINATION AND PENETRATION.

The next thing deemed of most importance is to fully comprehend that these parasites always germinate outside the plant tissues and gain entrance, if at all, only by mechanically penetrating the epidermis or other surface coat. An unsubstantiated opinion too commonly prevails that in some way the spores may be taken up by the roots with water and carried with the latter to any part of the plant. This assumption is founded upon a misconception of the manner that plants take water from the soil, and of the way it traverses the plant tissues. It is true there are in most plants elongated ducts or tube-like vessels, the open cavity of which is sometimes large enough to be seen in cross section by the unaided eye, and large enough to pass many fungus spores; but these cannot, in any just sense, be compared to the arteries and veins of animals. The truth is, when there is any considerable movement of the watery fluids in plants, these ducts are always filled with air, not with liquid material. If a sapling in full leaf, and consequently in its most active state as to the ascent of water to supply the marvellous amounts transpired is cut, and a portion of the stem thrown into water, the latter will be sucked into the tissues to the amount of 10 to 20 per cent of the weight of the green stem, clearly showing that the wood was not previously full. Other experiments and investigations prove that the water normally ascends (and descends sometimes) through the substance of the cell walls themselves, not through the cell cavities. Now, no one is able to see with the best microscope ever made the inter-molecular spaces in these cell walls, though water, itself made up of solid molecules, passes through them to gain entrance in the first place to the roots, and through the millions of them in its progress to the upper portions of the plant. No fungus spore can pass such filtering. The methods of freeing liquids from solid particles practised by chemists are coarse and sorely inadequate compared with that in operation in plants. It is absolutely impossible for any solid body large enough to be seen at all by the highest microscopic powers in existence to pass through one such cell wall, much less through the unnumbered myriads composing the tissues of one of our ordinarily cultivated plants. All spores of fungi rarely are less than one five-thousandth of an inch in diameter, while a body less than one hundred-thousandth of an inch can be seen and studied, and as the molecular openings through which water passes are still less, probably much less, we may be certain that such spores are effectually excluded from the circulation in the plant tissues. Direct examination also proves that the entrance of the fungus is affected by piercing the surface; the germinal tube accomplishing this by its power of absorbing the substance at the point of contact, or by reaching and passing through a stomato. A thick epidermis is often a complete safeguard against the former method, this alone being sufficient to account for the immunity of certain varieties from diseases which so nearly exterminate others. It is scarcely possible that any parasitic fungus should be able to make its way through the corky envelope of tree trunks, &c., which we call bark, so long as the latter is free from cracks or wounds.

It must be remembered that to exist a fungus is as dependent upon an organised structure as are other plants and animals. It is not possible that this solid structure can be dissolved and life continue; it is not possible that a fungus spore can be liquified, absorbed, and reorganised. As well might a criminal think of reducing his body by some chemical process to a liquid form in order to pass through the merciless grating of his cell window, and live afterward as a man.

As a practical demonstration of the non-absorption and non-circulation of fungus spores in the tissues of plants, nothing can be more satisfactory than the results as known of putting bunches of Grapes in paper bags to prevent the rot so prevalent in our country. These diseases, for there are several of them, are perfectly prevented by excluding the spores of the fungi which produce them from the fruit itself, though the rest of the Vine is not protected. As a matter of fact, other parts of the Vine are parasitised by the same depredators, and sometimes serious injury done; but the effect is necessarily different from what it is in the true pulp of the fruit. In these cases, and in most cases, the mycelium, or root-like portion of fungi, spreads but slightly from the first point of entrance, not more than a few hundredths of an inch in the stems and leaves, to a greater distance in the fruit. But a limited number of species uniformly send their mycelium very widely through the affected plant. Smut of Wheat shows itself only in the head, but the fungus starts in the germinating plantlet and traverses the whole length of the straw.

The conditions of germination are also important elements in a study of plant diseases due to fungi. The spores are very simple in structure; each consists of a single cell formed of an enclosed mass of plastic substance (protoplasm) around which are two coats, the inner thin and flexible, the outer usually thicker and much less elastic. In germination the outer is pierced or cracked, and the inner coat protrudes as a long tube containing still the soft internal substance. This tube is that which penetrates the plant, becoming perhaps a hundred times as long as

the spore before gaining access to the hypodermal tissues. A proper temperature, varying with the species, is essential for this process, but still more marked are the conditions respecting moisture. A fungus spore can no more germinate without water than can a seed of a flowering plant, though neither requires to be immersed in water. Damp air, such especially as we have during fogs, favours the germination and penetration of fungi. Sometimes these processes take place on leaves and fruit when more or less covered with little drops of dew. In bagging Grapes, should any of the rot-spores be included it is by no means probable that they would germinate on account of the want of water, and this is the secret af Grapes so often escaping the disease when the Vines are protected by being trained under the eaves of a building or similar shelter. This influence of water upon germination is one of the important reasons why most parasitic fungi make worse depredations during wet than during dry weather. In most cases the spores themselves are more readily and widely distributed when dry.

KIND OF INJURY.

The diseases caused by fungi present many peculiarities according to the species of parasite or of host. Sometimes the latter is simply enfeebled, grows slowly and slenderly as from want of sufficient nourishment, which doubtless is the fact, because robbed. On the other hand, the infested parts sometimes take on abnormal shape or size, the cells of the tissue swell to many times their proper dimensions, or become excessively multiplied, or excessively filled with nutrient material. Their normal functions are impaired or diverted, and curious deformations and transformations occur. Not unfrequently the abnormal growth, though very different from the healthy structure, is just as regular and characteristic, so that one who becomes acquainted with the peculiar development may be able to tell at once what species of parasite produced the odd cell-formation without seeing the fungus, just as certain galls on plants point unmistakeable to the species of insect which caused them.

This, or these, modifications of growth seem to be quite as injurious in many instances as the actual robbery of nutriment first mentioned; stems are swollen and knotted, leaves curled and distorted, fruit made unsightly worthless. But the worst effect of fungi is the more or less immediate death of the invaded cells. In well-known instances this takes place as regularly as the foregoing, certain destruction following the penetration of the mycelium, and affecting the rest of the plant or not, according to the location of the injury—if on the footstalk of a leaf, that leaf perishes, if at the base of the stem the whole plant succumbs. Sometimes a fungus seems to be so caustic in its effects that by merely creeping over the surface, sending down here and there, however, branchlets which without entering the epidermis act as suckers, the tissues beneath are destroyed.

REMEDIES.

It will be seen from the foregoing that there is much diversity in the physiology of fungi. A full account of the differences known in structure and habit would require a much fuller presentation of the subject than is possible here; but enough has been said to indicate, at least, that there can be no one method of fighting these invisible foes. The unfortunate thing really is, that with all the information yet attained, there is so little of practical value in the way of fighting them, after any methods. We can at least, however, understand many things which need not be done, and so save unnecessary expense and labour, just as the study of entomology saves men from stringing sweetened corn cobs and hanging them in trees to catch curculios. It is whimsical and futile to attempt any kind of medication of a plant by incorporating materials in the soil about the roots. Such applied substances will not usually be absorbed to any considerable extent unless, indeed, directly useful to the plant, and it may be safely said that no fungus parasite can be banished or even excluded by the presence in the tissues of any chemical substance thus absorbed, acting as a medicine. And the same may be said of any attempts at medication by directly introducing into the tissues by boring holes or otherwise, any substances whatever. The driving of nails, &c., into trees for such purposes is an admittance of ignorance, or it is quackery. In all this I do by no means assert that soil elements in certain cases cannot be added which may prevent or reduce the ravages of fungi; but, if so, these elements must be such as act by giving special thrift and quality of growth rather than as medicines.

We may understand, too, that nothing can be accomplished out of doors by fumigations or loading the air with strong odours. The impossibility of retaining even sulpher fumes sufficiently concentrated in the open air about plants to kill them should teach us that we cannot thus destroy an organism having so little dependence on pure air as a fungus. It is emphatically the exception, not the rule, that under suitable cover any such method of doctoring these diseases can be practised with profit. How hopeless, then, the case out of doors! So, too, it is usually useless to apply powdered substances to the affected plants in the hopes of ridding them of these parasites. Those who advise others from pretended knowledge still advocate in books and papers the application of flowers of sulphur to Grape Vines in our country to prevent or cure the "mildew" and "rot." How many tons of sulphur have been thus wasted! There is indeed one species of fungus (uncinuld), sometimes found on American Vines, which can be reduced in this manner; but it, at least in the West, is of little moment compared with any one of the three others that is not in the least inconvenienced by the sulphur as applied. In Europe this sulphuring has been found beneficial, but against the recently introduced American mildew (Peronospora) they have already discovered the antidote ineffectual. It is surely time that writers in our country should begin to understand that a successful remedy for one thing in Europe may not prove useful for another thing in the United States. The application of washes containing ingredients inimical to fungi has in some cases more effect, and when the special work to be done is understood positive good may follow. But even in this, too much dependence must not be placed for general use. Such washes are only applicable to the trunks and larger limbs of trees, and owing to the increase in diameter of the stem cracks soon occur in any such coating, after which the exposure is nearly as great as before.

Without further criticisms of such methods of prevention or cure, it may be stated that something can still be offered for special cases; but the prescriptions cannot be made general. In the first place, much in the way of prevention can be accomplished, has already been accomplished, by selecting varieties for culture which are not subject to the despoilations of injurious fungi. The orange rust (on the leaves) is very destructive to the Kittatinny Blackberry, but does not appear on the Snyder; the White Doyenné Pear is very often caused to crack and thus become useless by a fungus (Fusicladium) which often grows to some extent on certain other varieties without injuring the fruit in the least. Such illustrations are very numerous, and when observers learn carefully to discriminate different diseases they will rapidly increase. Season of growth, soil, and methods of cultivation and fertilisation may be usefully studied for the purpose now in view. It is not always the least vigorous plants, as so often asserted, that are most liable to rust, mildew, &c. Sometimes it is directly the opposite, as in the case of Wheat grown on land which is too rich. Certainly we must not suppose the plants need be in thriftless condition before fungi can grow upon or within them. There is simply some condition more favourable than others for the injurious development of the parasite. This special condition it is our business as skilful cultivators to find out.

There are some special methods of treatment, too, by which success may be gained. One kind of Wheat smut (Tilletia) can be effectually prevented by washing the seed with a solution of copper sulphate (blue vitriol); but this treatment for the rust on the straw is like smoking cigars to cure corns on the feet. The rust has nothing to do with the seed, but comes from spores passing the winter in the fields. Bagging Grape bunches and growing the Vines under shelter has already been referred to. Washing the trunks and larger branches of Apple and Pear trees with strong alkaline solutions, makes the bark smooth and much less liable to injury by what is improperly called sun scald. The fact is the

bark after such washing is a more certain barrier to living enemies, because more elastic and less liable to crack by the expansion of growth or from the alternations of temperature.

Something can be done, too, by directly preventing the development and dissemination of the spores. In numerous cases the winter is passed only by spores on or within dead leaves. Careful destruction of these may assuredly be very helpful. If one has an isolated vineyard he may do much toward freeing his Vines from fungus depredations by burning affected fruit as discovered and just before the leaves fall in autumn, pruning and burning all refuse, then the following season frequently picking off any diseased leaves, tendrils, fruit, &c., as the marks appear. This has been practically tried with excellent results; but it takes some labour and eternal vigilance. Knowing just how, where, and when to strike is important in any warfare, and advantages can frequently be gained in the kind of struggle now in question. In some localities Apple trees, especially certain kinds, are badly afflicted with a fungus on the leaves and fruit, which burrowing in the tissues causes a reddish or yellowish, usually a swollen spot, from which finally appear numerous cylindrical spore vessels, becoming with age fringed by spliting into threads. More or less injury is done according to the number of infested areas, often, however, utterly devastating the tree. This fungus (Gymnosporangia) has a regular alternation of growth on the Apple tree and the Red Cedar, forming on the latter balls sometimes mistaken for the fruit of the tree. These balls are an inch or more in diameter, and in May send out, when soaked with rain, conspicuous yellow gelatinous masses, which must have drawn the attention of all who have had the opportunity of seeing them. The battle would be a hard one against this species if fought only on the Apple, but on the Cedar it is by no means so difficult. The annually produced balls (galls) can be picked off, if so desired, without great labour from one or a few trees, or, what is still easier and more effectual, the Cedars can be entirely destroyed and the Apple orchard perfectly saved. Other such cases are known, and more may be by proper investigations. It has been proved that the rust of Wheat (Puccinia) has an alternate stage on the Barberry, and the latter has in some places been carefully rooted out on this account. But facts show that the Barberry cannot be essential to the development of this fungus, for the latter prevails in regions where the shrub is not present at all. Either the alternation is not essential or something else answers the place of the Barberry. Suppose this last to be the truth, which indeed is most probable, and suppose this unknown something to be as valueless to the farmer and as readily extirpated as the Barberry, what benefit—counted in money—would successful investigations confer! Is it not worthy of endeavour, fostered by governmental or other aid? And if so in one case, what shall we say of the hundreds in which the demand for information is still more urgent because less is already attained?—*Journal of Horticulture.*

Leaf-eating Ants.—Just round the house I at first attempted to make a more formal flower garden, and, to that end, planted countless Crotons, Jasmines, Hibiscus, Eranthemums, Roses, Colcus, Lilies, and innumerable other things. But at once an enemy came down on these. This was the leaf-cutting ant (Æcodema cephalotes), which is the true and almost insurmountable obstacle to gardening in these parts. Many stratagems did I try to prevent the vast hosts of these small beings, which walk and bring destruction chiefly at night. First cotton-wool was tied round the stem of each plant, and this kept off the ants until the wool, becoming soaked, was no longer fibrous, after which the ants walked freely over it. Next I tried to make a more durable minute fence round each plant by surrounding each with a strip of tin, the upper edge of which had been cut into a very fine and long fringe; but though if these were cut finely enough the ants did not pass them, they failed by preventing the plant from getting sufficient water round its crown. Then I put wider circles of tin round each plant, and put fresh tar on these twice a week; but this plan too, failed, partly because of the immense labour and considerable expense which it involved, and partly because the successive coats of tar flowed down and clogged the ground round the plants. Meanwhile, many attempts to poison the enemy were made and failed. Calomel was a delight to them; arsenic seemed their favourite food; carbolic acid pleased them, if possible, still more; and corrosive sublimate raised their spirits to perfectly terrible heights. All these new food substances seemed but to stimulate them to new exertions in the way of leaf-cutting. At last, in despair, I determined to remove the flower garden to a level space of ground by the side of the river after I had completely surrounded this with a deep ditch, to be kept always full of water. Ants apparently do not care to make their nests in the clay soil such as that at the river side; and the ditch prevents their making occasional raids into the new flower garden. So the plants there are now doing well. At some future time I may have something to report of them; but for the present my concern is chiefly with the wild garden on the hill.—E. Im Thurn, British Guiana.—*Gardeners' Chronicle.*

Gas Lime for Mossy Land.—On grass lands, where moss exists, gas lime is one of the best and cheapest remedial agents. According to the nature of the growth of the moss, it may be used either neat or mixed with soil. When used in its neat state it will not only take off the moss, but leave the land bare of vegetation, but the grass will return the following spring, sweet and good, and free from the moss. Where land is beginning to show traces of mossy growth, the best plan is to mix in the autumn equal parts of gas lime and soil—road scrapings will do. Turn it, and then apply in the following spring. Many parks, in the hands of gentlemen and noblemen, if treated in this way, would carry double the quantity of live stock they do at present.—*Land and Water.*

Manuring.—A question often occurs as to the amount of manuring which is most profitable to apply to land. A light dressing over a wide surface is by some believed to be best, while others insist on heavy manuring on a limited area. The question is answered by the manner in which the manure is applied. If merely spread on the surface and ploughed in, a wide and thin coat would be most profitable. A large mass would not become intermixed with the soil, and in a dry season might be worse than useless. Five thin coats, ploughed under in as many successive years, would be much better than one coat five times as thick simply turned under at one operation. A large amount may be applied in a single season, provided it is first finely broken and pulverised, and then intimately intermixed with the soil by repeated ploughing and harrowing, or on a small scale with the spade, hoe, and steel rake.—*Land and Water.*

Agricultural Education.—We reprint the following letter from the *Times* because it is as applicable in its way to horticulture as to agriculture, and the principles are the same in either case:—"A number of meetings have recently been held in Oxfordshire and Buckinghamshire with a view to the establishment of night classes during the winter for teaching the scientific principles of agriculture. There is a growing opinion among the more educated young men that agriculture requires something besides commissions and inquires and fair trade. It has been estimated that the annual waste from careless and unskilful methods of managing manure amounts to nearly £5,000,000. Add to this the want of knowledge in the purchase of artificial manures and their application, the waste of feeding stuffs, the odd pieces and corners of fields that might grow other things beside rank weeds and Couch-grass, and the waste of time in going to markets, auctions, and fairs. No industry can afford this general waste without difficulties, nor will any reduction of rent or local taxation, or increased price of Wheat, do anything for men who make no effort to improve their industry by increased scientific knowledge. The natural history of the wireworm, the leather-jacket, the dissolving of bones, the building up of plants, the judicious mixing of food, and many other things which farmers would be the better for knowing, can never be acquired by what is called practical farming. I would commend these classes to the consideration of the clergy and all who take interest in the welfare and education of young men in rural districts."—*Gardeners' Chronicle.*

Wood Ashes as a Manure.—Ashes improve all soils that are deficient in the principles which they contain, and are especially adapted to root crops, grains, and grasses. When applied in connection with bone dust, they produce, says a contemporary, excellent results on turnips, potatoes—all the roots in fact, clover, peas, beans, and the grasses. Ashes and gypsum mixed form an admirable dressing. Ashes are applied in a variety of ways. They may be drilled in the soil, sown broadcast, or mixed with the muck heap. Repeating the dressing of ashes without a sufficient amount of vegetable or yard manure will in time prove detrimental, but there is not much danger of this mistake. Coal ashes are decidedly inferior to those made from wood, and depend largely on their mechanical influence for value. They are better adapted to heavy than to light soils.—*Land and Water.*

Cocaine.—Our readers are familiar at least with the reputation of the Coca, or Erythroxylon Coca, the leaves of which are used as a stimulant, like Tea or Coffee, and which allay hunger and avert the sense of fatigue. This much has been known for years, and was put to the test by the late Sir R. Christison. Its properties were supposed to be due to a substance identical, or nearly so, with thein, the active principle of Tea and Coffee. Latterly this principle has been isolated, and has been found to possess such anæsthetic properties as even to render the eye insensible to touch. Its use in surgical operations is, therefore, likely to become very important and to be extended to tooth-drawing and other minor surgical operations. At present its high price forbids more than experimental use, but the results have been so uniformly successful that there is little doubt that as the demand increases the manufacture will be extended and cheapened.—*Gardeners' Chronicle.*

Aerial Motors of various forms have been devised, which adapt themselves automatically to changes in the direction of the wind; and the appended figure shows a recent foreign invention for this purpose (as well as for increased utilization of power), which is called the *pantanemone*, or "universal windmill. The cut is copied from *La Nature*, and shows merely a lecture-room model of the apparatus, designed to exhibit the principle upon which its construction is based. Two plane surfaces in the form of semicircles are mounted at right angles to each other upon a horizontal shaft, and at an angle of forty-five degrees with respect to the latter. It results from this, that the apparatus will operate (even without being set), whatever be the direction of the wind, except when it blows perpendicularly upon the axle. Experiment shows that it does about twenty per cent more work per year than can be obtained with other mills. Three of the machines are now working in France. The first of these has been running for nine years in the vicinity of Poissy, where it lifts about forty thousand liters of water to a height of twenty meters, every twenty-four hours, in a wind of a velocity of from seven to eight meters per second. The second raises about a hundred and fifty thousand liters of water to the Villejuif reservoir, at a height of ten meters, every twenty-four hours, in a wind of from five to six meters. The third supplies the laboratory of the Montsouris observatory. The machine is easily made and tested.—*Popular Science News.*

A New Application of Indiarubber.—Among the many curious and interesting things that attract the attention of the visitor to the Health Exhibition, now open in London, is a small boat, floating in a tank of water, and bearing on its deck a variety of glass and porcelain dishes. The water is thrown into commotion from beneath, and the boat pitches and tosses upon the waves; but the fragile cargo is not thrown overboard, as one would expect it to be. Are the dishes glued or cemented to the deck? or what is the secret of their mysterious stability? It is simply a new application of that protean substance, Indiarubber. A ring of the material, in the familiar "red vulcanized" form, is inserted in the bottom of each dish; and this makes it almost impossible to overturn the article. The table may be tipped at an angle of forty-five, and even of sixty, degrees, and yet the dishes will cling to it. The larger cut does not exaggerate the possible inclination consistent with stability. We need not say in how many cases this increased stability will be an advantage.—as in carrying dishes from room to room on trays, in giving food to persons sick in bed, and in the table arrangments of ships at sea. The "racks" on the table of the ocean steamer, the very sight of which, as some one has said, is "enough to make one seasick," may be dispensed with if these "irreversible" dishes are used. It may be added that the risk of breaking crockery, especially on the marble-topped tables of restaurants, is greatly diminished by this device; and the noisy clatter of dishes is well-nigh done away with—which alone would be a full compensation for the extra expense. We shall be surprised therefore, if this new application of Indiarubber does not soon win its way into general adoption.—*Popular Science News.*

Blue Gum Trees.—As showing the rapidity of the growth of our blue gum trees in California, the *Santa Ana Herald* says:—"A log cut from a blue gum tree on H. H. Roper's place has been sent to the New Orleans Expesition. It was of seven years growth, would weigh probably 500 lb.; and measured 3 feet through."—Melbourne *Leader.*

Cinchona Ledgeriana as a Species.—Mr. E. M. Holmes read a paper before the Linnean Society on Nov. 20, wherein he expressed the opinion that under the name of C. Ledgeriana a number of varieties or forms, and probably some hybrids, of Cinchona calisaya are now under cultivation in the British Colonies. He believed that if more attention were paid to the characters afforded by the bark of the trees, taken in conjunction with the other botanical characters of flower and fruit, these varieties and hybrids would be more easily defined and recognised. He considers that the plant published under the name of C. Ledgeriana by Dr. Trimen was probably referable to Weddell's Cinchona calisaya var. pallida as a horticultural form, for which the author proposed the name Trimeniana.—*Gardeners' Chronicle.*

Insect Pests.—A correspondent at Berhampore sends us the following:—"The werd *Sooa-poca*, put into English, would be the *needle-worm*. It gets this name from being covered with hair, each of which is from one-eighth to twe-eighths of an inch long, stiff enough and pointed enough to penetrate the human skin on the slightest contact, causing great agony, and if not extracted, a difficult thing, from its being so fine, as to be scarcely discernible to the naked eye, it causes a festering sore. One of my junior teachers came to school a short time ago with one of his fingers very painful, and much swollen, by one of these caterpillars having fallen upon his hand. They appear to grow from one to two inches in length, and are to be found in every garden and leafy spot in our part of Bengal. I expect, if you will tell any *malee* in Calcutta, he will bring you one for personal inspection. When matured, they climb up the garden wall, and under the projecting part of the coping weave a kind of web, in which you will find a number of their poisonous hairs. Under this web, which is very thin, you will find the chrysalis of the insect fastened to the edge of the wall. I suspect, the chrysalis turns into the common little white or yellow butterfly like these we, as boys, used to term the 'cabbage butterfly' in England. They injure leafy plants, but will not, I am told, touch the rice plant. Mango grafts are often damaged by them, and, if I remember right, I have seen them on rose bushes. Mr. J. has just come back from Plassey, and was telling me a few hours ago, that the lentile, known as *urhur* or *ruhur* along the river bank, was eaten up by them, the pods not being touched. He saw them in large numbers crawling down to the water's edge, senselessly entering into the water to be devoured by the fish. He was struck with the peculiarity of their all going in a westerly direction. I sent for an old rustic about 65 years of age, and sought information on the point. He said, he had intended, but had forgotten to tell me, that when on an errand last week, he saw large numbers of them, all proceeding in a westerly direction near the large tank in the station. They were common, he said, injuring leafy plants, but he had never observed them in such large numbers. My rustic informant could not say anything about the best method of dealing with them, but suggested, that perhaps lighting fire and smoking them might answer. I asked, 'how will you make fire in a lentile crop?' He smiled, and said, that was true, and when they came in such vast numbers, what could be done."—*Indian Agriculturist.*

Correspondence.

To the Editor of the "Ceylon Observer."

CUCA SEED AND CINCHONA GRUBS.

20th Feb. 1885.

Dear Sir,—I' m a native of the "Emerald Isle" and am almost as green as the auld counthry.

I 've chosen a small bit of land on the higher ranges of North Travancore as a field for investment, "for a rayson I have" in preference to other parts of the globe.

It 's all very fine for Ceylon planters to be called enterprizing etc.—no doubt they are so,—but, as the whole island is interested in planting, more attention is given by the mercantile portion of the country to planting interests than here in India. Now, if a Ceylon man wanted some "cuca" seed, I 've no doubt he 'd know where to get it; but, although I 've written to most places in India where I thought it possible to obtain that seed, I have failed; the Madras Agricultural Society have three or four plants, which I am to have in the course of time. Having failed in India, maybe some planter in Ceylon, who has been more fortunate than myself in getting the seed, can tell me where he got it, and, if he thinks there is more, where that came from? I have no doubt that the attempts of Indian planters to be "enterprizing" have been constantly nipped in the bud, because of the comparatively few firms who are equally enterprizing.

I have noticed a large percentage of my seven-month old cinchonas ringed at the collar by a dirty-looking grub; forgive my asking you the scientific name of the spalpeen.—Yours truly,

SHAMROCK SO GREEN.

[Will correspondents answer?—Ed.]

TWO ACREAGES.

Sir,—In former days we outsiders of the coffee world were always in doubt when we heard of large yields of crop. Conscientious superintendents used to estimate the breadths of cultivation: A field 30 to 40 acres, B 20 to 28, C 50 to 60, and so on. When they talked of crop, the minor extent was always paraded. "I got eight hundred hundred-weight off my little place of 100 acres." The proprietor however could not quite see it in the same rosy light, he found that to encourage kulis liberal contracts were given and found he was charged for about a hundred and thirty-two acres of weeding somewhat in excess of the major breadth.

Of course the flights of experimental incursions on hearers' credulity by imaginative managers were regulated by no hard-and-fast rules. Now, what I want to come to is this: how can my friend X. came to a fair estimate of the probable returns of an investment? He has several intimates: some will show their books, but, being economically inclined, have not had their different fields measured, and are going on guess-work. Some do not think it right to show the cost of working. Others again have partially abandoned fields and guess again how much of each is in tea. If a few straightforward men, who do know how much each field contains, would publish results trustworthy, the matter would lie in a nutshell—such as are given by Abbotsford, for instance. We want more such, so as to be able to strike an average. It is easy enough to calculate profit by the theoretical "Getting five hundred pounds an acre and selling at sixty cents equals a profit of fifty per cent," but in Algebra x's are unknown quantities, and in the above equation we have nothing else. How can anyone say that an acre will give hundred pounds, averaging sixty cents in value?

B. B. B.

[The yield of 500 lb. per acre was taken by us as a medium between the 400 lb. and 700 lb. estimates for high and low estates respectively, and we allowed for a fall in price to 10d per lb. A "devil's advocate" however, for the duties of which office our correspondent is eminently qualified, has his uses, and so we submit this letter as an incentive to accuracy in stating acreage.—Ed.]

HELOPELTIS ON TEA.

Sir,—Considering the importance of tea as a substitute for our declining old staple coffee, everything affecting its future in Ceylon becomes of the very highest interest to the planting community. It is therefore with much concern that I have to inform you that I have lately had to cut down several acres of tea owing to a severe attack of Helopeltis. I have known of the existence of this pest on tea for some months past. But, as the mischief done has generally been of slight extent, I have not called attention to the facts as I was unwilling to create alarm, but now I think it my duty in the interest of the enterprize to state the fact as abovementioned in order that tea planters may be on the alert and watch the first symptoms of attack, and use such means as they may deem best in their defence.—Yours faithfully,

OLD PLANTER.

[We believe the scene where the pest has appeared so badly is in the south of the island. On Abbotsford where one *helopeltis* was found, we have heard of no second specimen. Experience with cacao seems to show that the evil can be coped with. In an Eastern district, we learn children gather and destroy the insect.—Ed.]

TEA DRIERS: "SIROCCO" *VS.* "KINMOND."

Ambagamuwa, 6th March 1885.

Dear Sir,—The discussion between the patentee of the Kinmond drier and the local agents of the "Sirocco" is calculated to benefit the tea planters in general, and therefore I do not hesitate in responding to a call by the latter to support the "Sirocco." I cannot add to what has already been said by so competent an authority as Mr. Armstrong of Rookwood; but I would point out, that, although the "Sirocco" is capable of a high degree of temperature, most authorities on tea prefer firing at 270 degrees, where there is no absolute call for quick drying, caused by pressure of leaf on hand. This would apply equally to Kinmond. But what is of importance in comparing the respective prices of the two makers has, I fear, been lost sight of entirely, and that is the cost of power to drive the fan in the Kinmond. The champion for the "Sirocco" should add the value of water-wheel, pit and pipes or gutters, tank, etc. etc., and wear and tear of these supplementary items as indispensably connected with this drier; also, for estates where there is no water, the cost of engine, fuel, wages of stoker, wear and tear, etc. There will be an appreciable difference, I think, in favor of the "Sirocco." But we have not seen enough as yet of the No. 3 Sirocco, I think, to dispose of the question thus summarily at this stage. If in the course of the year it be found that the No. 3 is as satisfactory in its working as the old "Sirocco" has been, plus the larger cutturn, then I am inclined to think that the tea planters of Ceylon will spare Messrs. Davies & Co. the trouble of wasting their spare time in discussing the respective merits of the driers for *our sole* benefit! My friends will not take offence at the playful remark in conclusion.—Yours truly,

AGRICOLA.

"AND TEA AND CINCHONA REIGNED IN ITS STEAD."

Colombo, 9th March 1885.

Dear Mr. Editor,—Some two years and four months have passed since I addressed you under this heading, my object having been to afford my testimony to what was then almost an acknowledged fact, that the reign of King Coffee was at an end, and that tea and cinchona had succeeded him. Very few planters ventured to dissent from this view, but one gentleman hailing from Lindula (not Logie) rather ridiculed the idea of coffee being done for.

Since I wrote to you, I have been to England and have only very lately returned to the Island, where, I am sorry to say, I am rather deeply interested in coffee planting. I have just come back from an excursion over nearly the same line of country that I visited in 1882, viz. Dimbula, Lindula, the Agrapatanna, Pundaluoya, Nuwara Eliya, Udapussellawa, Ramboda, Pussellawa, Atabage, and Gampola.

I need hardly tell you that I found the new cultivation more firmly established than ever, and in most districts there was every sign that coffee was gradually dying out.

I fear that leaf-disease is by no means on the wane, and that it is too surely undermining the constitution of the coffee trees. It is true that there are a few districts, such as Dimbula, Lindula, Pundaluoya and a few others, where coffee can still be made to give a small return, but these are exceptions, and I much fear very few are even self-supporting, especially with the low prices ruling at present.

The appearance of the young tea plantations is, on the other hand, most encouraging. Tea seems to grow everywhere. The clearings in Ramboda and Pussellawa are especially very extensive, in fact those districts may be said to have abandoned coffee, which is gradually dying out. What with tea and cinchona the appearance of this part of the Island is quite altered, but the same may be said of most other parts where once upon a time coffee reigned supreme.

What struck me very strongly during my travels, was the evident want of capital. Even good coffee, where it exists, is not cultivated properly. Pruning is little attended to, and as to manuring very little is being done.

I could not fail to notice that on those estates where these operations are performed satisfactory results have followed in the shape of crop. I know of three properties lying in a line, with which I am intimately acquainted, where one is highly cultivated and has the largest crop in the district, the next is fairly well cultivated in the way of pruning and manuring, and has a paying crop—the third has a miserable crop in consequence of expenses having been cut down to a minimum, and leaves a heavy loss.

With regard to tea, I should mention that the unusual dry weather for the last two or three months has seriously affected the growth of the November and December planting, and that the young plants have made scarcely any growth, as far as I could see.

It is a great pity that the want of money is obliging many planters to harvest their bark at a time when the European markets are becoming over-supplied. Those who can wait a little should certainly do so. The bark will improve by age, and will probably meet a better market a few months hence.

Altogether I have been most favorably impressed with the wonderful progress that has been made in planting of new products during the last two years, and am lost in admiration at the skill and energy displayed by our planters, in contending with the difficulties which have opposed them, by the want of confidence in capitalists and the consequent scarcity of money. Success, I feel assured, must eventually follow and Ceylon again become a thriving and prosperous country.—Yours faithfully, G.

[A few days ago we met another old Ceylon resident who had just completed an extended tour over high country and low, and he was enthusiastic regarding the rapid progress and the assured success of the tea enterprise. In former times he had profited by coffee as he is certain he now will by tea.—Ed.]

THE BEST METHOD OF FERMENTING TEA.

[The following letter addressed to a Young Ceylon Planter has been sent to us for publication.—Ed.]

Colombo, 11th March 1885.

My dear ——,—The difficulties of which you complain in properly fermenting your teas, have set me thinking on the subject.

Unfortunately, as yet I know nothing practically about fermenting tea, and I have here no means of experimenting. I think I will write to the newspapers, suggesting that the P. A. or C. of C. should offer a prize for the best method of fermenting tea, or rather for the best sort of room, temperature, or climate for fermenting it, so that the time occupied in the process should be the same all over the island, in all weathers, and at all elevations.

It is to be done, I should think, by constructing fermenting rooms, which could always be kept at a uniform point of temperature and humidity for the object in view. If a warm moist climate is necessary, a little steam from a kettle would give the necessary humidity. See in England how in green or hot-houses they make any climate they want! Why, when our tea leaves won't wither or ferment properly, do we blame the weather, or the drafts of air in the store or the roof, instead of our own want of ingenuity?

Set your mind to work, ascertain what is the best temperature, the best sort of climate (moist or dry), and then make a room the air of which could be made exactly to suit your purpose.

There is but one mystery connected with the proper manufacture of tea, and that is the fermentation, as everything depends upon its being properly done. Surely, amongst so many intelligent minds the problem can be solved.—Yours, &c., ——

COST OF GATHERING, MANUFACTURING AND PLACING TEA F. O. B. COLOMBO.

Strathellie, Nawalapitiya, 30th March 1885.

Dear Sir,—Mr. Rutherford, in his letter on the cost of manufacture &c. of tea, expresses a wish that others using machinery should give data based on experience. The following are the actual figures of cost on the past season's working here with Jackson's Excelsior Roller, Ansell's Sifter and Davidson's No. 1 Sirocco. Facilities of transport give Mr. Rutherford's estates a slight advantage, but practically the cost of plucking, manufacture and placing f. o. b. in Colombo are the same:—

	Cents.		Cents.
Plucking, including baskets and transport of leaf . .	10·36	against Mr. R.'s average of	10·31
Rolling, firing, sifting, and packing including boxes, and tea-house sundries ...	5·47	„ „ „	5·54
Transport to Colombo and charges	1·86	„ „ „	1·75
Total cost of manufacture f. o. b. Colombo... ...	17·72	„ „ „	17·60

—Yours faithfully, ARTHUR E. SCOVELL.

[The close coincidence of the results is certainly striking; but we hope the figures may be brought down to 15 cents.—Ed.]

Ratmalane Estate of 350 acres of cinnamon and coconuts situated at Ratmalane, which formerly belonged to the late Mr. A. Gun has, we learn, changed hands—the lucky purchaser being Mr. C. H. De Soysa and the consideration £4100 sterling. The price is thought a fair one as times ago. The average is £11·10 per acre all round for cinnamon and coconuts. Miss Stubbs is the vendor, Colonel Meaden being the local agent.—"Examiner."

Erythrina Indica in Colombo.—One morning we noticed, not crows but squirrels, the common ground thrushes and little tomtits all busy getting *something*, nectar or insects, out of the flowers of an Erythrina. They were *not* eating the petals. We have never as yet noticed the sunbirds, those true nectar-suckers, meddling with the *Erythrina* blossoms, and, as we know the squirrels eat white-ants, we cannot help suspecting the attraction was in the shape of insects.

Paper Bottles are now made on a large scale in Germany and Austria. The paper must be well sized, and is composed as follows:—Ten parts of rags, forty of straw, fifty of brown wood pulp. The paper is impregnated or coated on both sides with sixty parts of defibrinated blood, thirty-five parts of lime powder, and five parts of sulphate of alumina. After drying, ten or twelve rolled leaves are coated again, placed over each other, and then put into heated moulds. The albumine of the blood forms a combination, on pressure with the lime, which is perfectly impermeable to spiritnous liquors. These bottles are made in two pieces, which are joined afterwards.—*Burgoyne, Burbidge, Cyriax & Farries' Price Current.*

Indian Tea in Holland is thus noticed in the *Indian Mercury*:—With regard to British India tea, which, since the Melbourne Exhibition of 1880, has been placed on our market (with the assistance of the British India Government), and whose advocates made such a fuss about, we can but say that our anticipations and hopes regarding its success have not been realized. The importation of this special kind to Holland amounted in 1882 to 1,000,000 English lb., whilst in 1883 only two shipments came to hand, together 1,400 chests of 40 lb. each, and this year we have not received a single case. Indian teas, notwithstanding the energetic and efficacious way in which their sale in Holland has been pushed, have made no headway—in fact, they were pronounced too strong for the public taste, the consumptions gradually diminished and prices declined. The loss on the last shipments has therefore been very heavy. However, as two well-known houses here are now beginning to mix British Indian quality with China teas, we may still hope, later on, to work up a fairly good trade in the article with India.

Flavouring Tea with Flowers.—(Extract from from Mr. Holmes's letter of 13th Feb. 1885 regarding Ceylon Tea sent to him)—I think, that, if the flowers of *Camellia sasanqua* were added, it would improve the flavour. The Japanese use this plant for the purpose. The Ceylon tea to my mind has too much of the flavour of half-decayed or fermented leaves. However, that is a matter of taste. The Chinese, I believe, flavour their tea with flowers of *Olea fragrans, Jasminum sambac,* and *Chloranthus inconspicuus.* [The above extract of a letter from the Curator of the Pharmaceutical Society has been sent to us. The specimen of Ceylon tea sent to Mr. Holmes must have been inferior, or he must be a bad judge. For a list of flowers used by the Chinese, see Mr. Brace's Essay published at the *Observer* Office. We spoke to the late Dr. Thwaites about using flowers, and his opinion was adverse. We have never heard of Indian or Ceylon planters using flowers.—Ed.]

Plumbago in Aberdeenshire.—Mr. Ferguson, of Kinmundy, read a paper before the Edinburgh Geological Society at the last meeting 'On certain Deposits of Graphite and Iron in Aberdeenshire.' Details were given of veins of hæmatite iron and manganese which are very extensive, and many of the veins were found to be as rich as the Spanish ore. Plumbago is plentiful, the only question being its production and transport so as to be used economically.—*Athenæum.* [Mr. Ferguson's paper ought to be of interest to us in Ceylon: who amongst us knows the Laird of Kinmundy well enough to ask him to allow the paper to be reprinted out here?—Ed.]

Darjeeling.—A fair amount of rain has fallen during the last ten days, and it goes without saying that it has done a deal of good to all kinds of crops in the district. More rain is needed though for tea cultivation, and especially so where large areas of seed at stake have been planted out. With regard to tea it is quite impossible to venture even a guess as to the result of the last season's working on gardens which have shipped their teas to London direct as a good deal has still to be sold, but it may very safely be anticipated that a few gardens will pay a fair dividend not at all equal to those realized on the crop of 1883, but still enough to keep the pot boiling, and that is saving a very great deal in these hard times, and considering how tea has been depreciated in the market. It is pretty generally acknowledged by practical men that the first invoices of last season's teas from this district were not in some respects quite as good as those of 1883, but at the same time it is very generally considered that the teas were often sold under their real value. Certainly there was none the less care in manufacture, and it was the misfortune not the fault of the vast majority of planters in the hills that the market was more or less disorganized the whole of last year. Rigid economy seems to be the order of the day for the coming season. It remains to be seen whether the economy will be carried out in the right direction or not.—*Indian Planters' Gazette.*

Roraima.—A telegram has been received at Kew giving the welcome news that Mr. Everard F. im Thurn has at last ascended Roraima. This has been the cherished object of botanical exploration in South America for the last quarter of a century. The expenses of Mr. im Thurn's expedition have been borne in equal shares by the Government grant of the Royal Society and the Royal Geographical Society. The latest news from Mr. im Thurn was in a letter dated December 6th from the south side of the mountain, and the following passage describes the position immediately before the final attack:—"Before we came to Roraima itself we had four days' walking through a purely savannah, but most glorious, country and over splendid mountain passes, guided by an Arecoona, who said, villain that he is, that he knew the way to Roraima. But at a village marked on the map as Ipelemonta, on the Aroopa River, and with a considerable mountain pass still between us and Roraima, our villain guide at last admitted that the road for some distance had been quite new to him, and that he now knew not how to proceed further. However, at last we procured a guide, and came, in some four hours, out of our difficulties at Ipelemonta (its real name, by the way, is Toorarking), into this inconceivably magnificent valley, and are installed in a village on the actual southern slopes of Roraima itself. Yesterday Perkins and I ascended the slope of Roraima to a height of 5,600ft. to a most beautiful spot—a very garden of orchids and most beautiful and strange plants. To-morrow, after despatching the bearer of this scrawl, we go up to the same place with a lot of Arecoonas, who are to build us a house, in which we intend to stop for a week, or as much longer as we may find desirable. I may mention that we have already seen, close to where our house is to be, a place where the mountain seems accessible; but it looks so easy that I am convinced it is impossible at that point."—*Nature.*

PLUMBAGO: ITS GEOLOGIC AGE AND ORIGIN.

The writer in the local "Times" who, over the initial R., wrote recently on the geology of Uva, in which he included "trap" rock, a volcanic product in a country believed as yet to show no definite signs of volcanic action, now expresses doubt regarding ourd quoted statement that plumbago is amongst the oldest formations in the earth's crust. If belonging to the primitive series of rocks, then, R. asserta, it cannot be of vegetable origin:—

On the other hand, the existence of plumbago in the oldest known formations being admitted would lead me to the supposition that it is some chemical elimination formed in the bowels of the earth, from the fact that graphite or plumbago is produced in the manufacture of cast iron, separating from the molten pig-iron in the form of scales.

As. R. desiderates the latest information regarding rhe mineral of which, in an available state, Ceylon has almost a monopoly, we may ask him if he has tead Professor Armstrong's article on Carbon in the new edition of the *Encyclopædia Britannica*; because in that article, natural plumbago and that obtained from iron furnaces are stated to be essentially different. On the other hand the identity in constituents of plumbago and the most b eautiful and precious of all crystals, the diamond, seems to be assumed at the very commencement of the article:—

Carbon (*symbol*, C; *atomic weight*, 12) is one of the most important of the eemical elements. It occurs pure in the diamond, and nearly pure aa graphite or plumbago; it is a constituent of all animal and vegetable tissues and of coal; and it also enters into the composition of many minerals, such as chalk and dolomite.

Carbon is a solid substance, destitute of taste and odour; but it occurs in several modifications which exhibit very diverse physical properties. Thus, it is met with in the form of the diamond in transparent crystals belonging to the regular or cubical system, which conduct electricity but slowly; and in the form of graphite in opaque crystals belonging to the hexagonal system, which conduct electricity nearly as well aa the metals. The diamond is the hardest substance known, and has a relatively high specific gravity (3·33 to 3·55), but graphite is comparatively soft, producing a black shining streak when rubbed upon paper and has a much lower specific gravity (2·15 to 2·35). In addition to these two crystalline modifications of carbon there are a number of varieties of non-crystalline or amorphous carbon, which, however, exhibit the greatest differences in physical properties.

By heating to the high temperature afforded by a powerful galvanic battery, both the diamond and amorphous carbon are converted into graphite. In the election are carbon appears to be converted into vapour; but the temperature which is required to volatilize it is extremely high; in fact, it has been calculated that the boiling-pnint of carbon is not less than about 7,000° on the centigrade scale.

Experiments are then described under which the diamond remained intact, but the an orphous carbons were converted into "a *humus*-like substance":—

Or "humic acids," *soluble* in water, whereas the different varieties of graphite furnish "graphite oxides," which are *insoluble* in water, and especially characterized by the property of undergoing decomposition with deflagration when heated.

Then follows the statement:—

Berthelot has examined a very large number of varieties of carbon in this manner with the following results. The carbon of wood charcoal, animal charcoal, coke, the so-called metallic carbon obtained by decomposing hydrocarbons by passing their vapours through a red-hot tube, gas-retort carbon and various specimens of anthracite from different sources all dissolved entirely with more or less readiness when treated in the above manner; lamp black, however, furnished a small amount of graphite oxide. The amorphous carbon of the meteorite of Cranbourne (Australia) furnished a graphite oxide identical with that obtained by similarly treating graphite from cast-iron, but the carbon of the Orgueil meteorite was entirely soluble. The carbon of the Greenland meteoric rock discovered by Nordenskiod also dissolved entirely with the exception of a very insignificant residue.

On examining the pencils of carbon employed in producing the electric light it was found that the spongy mass of carbon collected on the negative pole contained a large proportion of graphite, but that only traces were present in the pencil employed as positive pole, which appears to indicate that it is necessary for the carbon to undergo volatilization in order that it may be converted into graphite. The graphite thus produced is not identical with that contained in cast-iron, nor with natural plumbago; the same variety of graphite is produced, however, when the diamond is heated in the electric arc.

Then comes a separate notice of "graphite" which we quote in full:—

Graphite.—Graphite is found native near Travancore, in Ceylon, and near Moreton Bay in Australia, in several parts of the United States, in South Siberia, and in Germany, principally at Griessbach near Passau, always in rocks belonging to the earliest formations. It occurs in two distinct modifications, one of which, like the Borrowdale graphite, is fine-grained and amorphous; the other, like the Ceylon variety, is composed of small flat plates. Native graphite contains from 95 to nearly 100 per cent of carbon, the impurity being usually small quantities of silicates. Graphite, also called plumbago or black lead, is used for making so-called lead pencils, for polishing iron work, for lubricating machinery, for making crucibles, and in the electrotype process for coating the surfaces of wood, plaster-of-paris, gutta-percha, and other non-conducting materials, so as to render them conductive.

The behaviour of graphite on treatment with a mixturr of potassic chlorate and nitric acid has been carefully studied by Brodie; but our knowledge of its oxidation products is still very incomplete. He has shown that it is converted into a body to which he attributes the composition indicated by the formula $C_{11} H_4 O_5$; *graphitic acid*, as this compound is termed, forms yellow silky plates, insoluble in water and acids. It does not form salts, and Berthelot therefore prefers to call it *graphitic oxide*. When this substance is heated it decomposes almost with explosive violence, leaving a residue which still contains hydrogen and oxygen, but which is not distinguishable from finely divided graphite. When the graphite which crystallizes from cast-iron and that obtained by heating amorphous carbon in the electric arc are similarly treated, graphitic oxides are produced which differ from each other, and from the oxide formed from native graphite; it is therefore supposed that these graphites are distinct substances (Berthelot, *Ann. Ch. Phys.* [4] xix. 399).

"Always in rocks belonging to the earliest formations" writes Professor Armstrong, and he quotes from Berthelet the statement that the graphite which crystalizes from cast iron, that resulting from heating amorphous carbon in the electric arc, and native graphite, are different substances. There is certainly no room to dogmatize on the subject, but we stil lean strongly to the opinion that graphite is aa muel derived from vegetable matter aa is anthracite or true coal. Who can say how early in geologic time vegetation in the shape of ferns, mosses and similar forms appeared on the earth, and how completely chemical changes enabled carboniferous matter to resist combustion?

Of the intimate bearing of plumbago, its constituents and formation, on the theory of the crystalization of amorphous rock, we can have no doubt, any more than that the two great agents at work were heat and pressure, with resulting magnetic attraction. If plumbago could but speak it could a wondrous tale unfold of changes sudden and violent and processes continued through centuries of ages, before it assumed its present shape and character.

Talking of the earliest rocks and their constituents, what has R. to say about the modern theory that granite is derived from gneiss? When we first dipped into geology, the stratified rocks were represented as deriving their origin from granite. But *quien sabe*? Those who know most are the first to confess how little is yet known of the history of the earth we tread upon.

SUGAR AND COFFEE IN NETHERLANDS INDIA.

(*Translated for the "Straits Times."*)

Mr. Van Deldeu Lacrue, who was lately commissioned by the Netherlands Government to report upon coffee growing in Brazil, recommends to the same, on the strength of his experiences there, that State coffee cultivation in Java should be made less burdensome on the people, and be only proceeded with on land proven to be suitable for it on careful inquiry, the yield to be delivered uncured by the natives at great central establishments of at least ten thousand piculs storage capacity, where its preparation for the market shall be carried through on Government account, the Government also to do everything in its power to push the sale of Java coffee abroad, especially in Russia and Central Asia, to encourage the collection of statistical information regarding coffee cultivation and the coffee trade in Java, and enable the Java Bank to lend money on hypothecation.

Owing to the sugar crisis, many European overseers have been dismissed from Java sugar estates to make room, in some instances, for Chinamen at lower wages. Two of them have left for Australia to try their luck in that quarter, on the understanding that they would send back word should success attend them, many others being ready in that case to follow their example. The Sourabaya *Courant* affirms that molasses sugar has fallen there in value to two guilders per picul. Two wealthy planters have determined to keep their white sugar in warehouses, in hopes of that article soon rising in price. The disadvantage attending this course is that, after one year and a half the sugar falls off in quality, changes colour, and becomes less sweet.

MAURITIUS.

THE FUTURE OF SUGAR AND OTHER CULTURES.

(From the *Mercantile Record and Commercial Gazette*, 16th Feb.)

If when every imaginable economy has been effected on sugar estates,– the wages of the indians reduced to 5 or 6 rupees per month, for the 1st and 2nd class best labourers, the rations reduced to the lowest figure, the salaries of the sirdars, and all the *employés* lowered in the same proportion. After all this has been done, supposing sugar not to rise in price so as to be able to pay for its own cost in making; and compelling all those who depend upon it to seek some other employment; supposing all this to come to pass, we ask what will be done with the mills and sugar-house machinery, which have been the principal cause of the sugar-estates being so deeply indebted, which will be left standing and only a part of them salable at very low prices to perhaps Australia, what we ask, will be done with the buildings of the sugar houses &c.?

We ask these questions, for we have certain misgivings that, although sugar may *now and then* be sold at a paying price, *i. e.*, that the sale-price may pay for the cost of making, giving a slight profit, the general ruling prices will be of less than cost-price If the average of the occasional slight rise and of the occasional slight fall is in the long run only equal to par, sugar-making must be given up as a losing game, unless very superior agricultural chemistry of which we spoke yesterday, can turn the balance.

Russian Duty on Tea and Oil.—From the London *Times* we learn that the Board of Trade have received through the Secretary of State for Foreign Affairs a despatch from Her Majesty's Minister at St. Petersburg, enclosing a translation of a decree of the Russian Government, dated Jan. 20-Feb. 1, 1855, increasing the rates of import duty upon the following, among other articles :—Tea, imported at European ports, and across European land frontier, per poud, 21r. (gold) (£10 6s 11d per cwt.); olive oil and all vegetable oils (except coconut, palm, &c.), bone oils, fatty and empyreumatic oils, and olive oil with admixture of turpentine, per poud, 2r. 20c. (£1 1s 8d per cwt.). These increased rates of duty are levied on and from the above-mentioned date.

Encouragement to grow the Pepper-vine.—There are not two articles in the spice trade, says the *Home and Colonial Mail* now so dear as black and white pepper, and there are good, reasons why the prices ruling should be comparatively high. For some time past, chiefly in consequence of diminished imports, stocks have been working down into a narrow compass, and as it is between the seasons now, two or three months must elapse before any material addition to the supply on offer, by fresh arrivals, can possibly take place. Even then the quantities on hand will require so much replenishing that large proportions of the quantities put forward will be quickly absorbed for that purpose, and still further heavy importations would be necessary to bring the value down to a more moderate level than it has stood at for years past. With few landed parcels offering, the bulk of the business done for several weeks running has been for January or "distant" shipment at stiffening rates, till Acheen, Penang, has fetched 7d, and Singapore black 7⅞d to 8d per lb. It is believed that on the Continent the same scarcity prevails, as at Havre, for instance, only about 8,300 bags are held by the importers, in contrast with 22,700 bags at this period in 1884; and the exports from hence are a much-needed supply drawn away from this side. The same remarks apply to white pepper, which is also very scarce, and is likely to be much dearer before the market is adequately supplied, as its manufacture by the natives in the East is sure to be interfered with or delayed while black descriptions of pepper command advanced prices such as those now existing. Indeed, if it were not for the London-made sorts of white pepper which are regularly produced, there would doubtless have been another and more considerable rise in value long ago; and as a sign that there has been no accumulation of supplies in the hands of sellers, we may mention that it is some months since anything of importance pertaining to this kind of pepper was offered for sale by public auction.

Lyle's Improved Tea Roller.—Perhaps the next best thing to a new invention is an improvement on an old one, especially when such improvement is accompanied with reduction of price. We are able to notify that the combination of advantages has been attained by the proprietors of Lyle's Rolling-machine. The former price of £85 f. o. b. in London, or R1,200 in Calcutta, has now been reduced to £70 and R1,000, respectively. The present machine is stronger in make than the original one, and can roll off a larger quantity of leaf. Eight maunds of leaf can be double-rolled in an hour, or 12 maunds single-rolled in the same time. This is very rapid work, but the leaf has a good twist, and those who have used the machine say that the outturn in the cup is always of a very even colour. The machine is remarkably simple in construction, and cannot well get out of order. The pressure can be regulated at will, by a ratchet movement. This is a great desideratum, as the tendency of some machines is to smash the young leaf or insufficiently twist the hard pluckings of the finish of the season. Although the model we were shown is for steam power, the machine can be readily fitted with a fly-wheel for hand-driving: and as no foundation is required, its erection is simple and cheap enough. Mr Kirwan, the superintendent of the Doom-Dooma Co., says that he considers the outturn of infused leaf brighter from this machine than from any other. This is high praise, as we all know how prices are affected by the colour of the infused leaf. As to working capabilities, the machine can roll 100 maunds of leaf daily and no hand finishing is required.—*Indian Tea Gazette.*

THE FRAUDS IN THE MADRAS CINCHONA DEPARTMENT.

Noticing the recent trial and conviction of a couple of subordinates in the Madras Cinchona Department, the *Madras Mail* writes:—

"The late Mr. McIvor was entrusted with the introduction of cinchona cultivation in the hill districts of Southern India, under the advice and guidance of Mr. Clement Markham, to whom this special duty for all India was assigned by Her Majesty's Government; and at the time of his death in 1876, seven estates had been opened on the Nilgiris,—namely three at Neddivattum, two at Pykara, one at Ootacamund and one at Nevelkoondah,—the whole covering an area of 1,200 acres and numbering 1,190,458 cinchona trees, including half-a-million each of officinalis and succirubra, estate. In 1871, all expenditure on the Nevelkoondah was discontinued with the object of ascertaining how far cinchona could be left to nature. In 1876 the Madras Government recorded an expression of complete satisfaction with the progress of the experiment, and its belief that the objects in view of providing an abundant and cheap supply of the febrifuge for the use of hospitals and troops in India, and of encouraging the cultivation of cinchona, were in a fair way of being realized. Shortly before Mr. McIvor died the Quinologist, Mr. Broughton, had mysteriously disappeared, and although this gentleman is said, at this moment, to be in New Zealand, no communication has ever been received from him by any of his friends in this country and there are many persons who will not credit the rumour of his being still alive. The appointment of a Quinologist had been advocated by Mr. Markham in 1866, but Mr. Broughton was not appointed till the latter half of 1868, and he held office till 1875 when the post was abolished, the report of a Commission specially appointed to investigate the subject having satisfied the Government of the day that a Quinologist was an expensive encumbrance. The Ootacamund laboratory had consumed during the seven years it was in operation no less a quantity than 362,050 pounds of green cinchona bark, valued at R.59,930, in producing 922 lb., of "amorphous quinine," or at a cost of 130 shillings per pound. The Quinologist's Department had further spent R.128,681 to the end of 1875 in salaries, plant, and establishment, and had generally failed to secure the purposes for which it was constituted, namely, to investigate the various questions connected with the elaboration of alkaloids, the best methods of harvesting the bark, and the most economical and efficacious mode of preparing the febrifuge.

"In 1877 Government apprehended that all was not right with the plantations, that their contents had been overstated, and that the expenditure was not judiciously incurred. Captain Campbell Walker, Inspector of Forests, was deputed to make enquiry into these matters, and to suggest measures for the future management of this valuable State property. His enquiries disclosed the fact that there was a considerable deficit in the number of plants said to be established on the various plantations—there being little over 700,000 instead of 1,190,458 borne on the returns. His report, however, was not adopted in its entirety though the Government was convinced of the great laxity that had prevailed in the administration of the Department for which it accepted a large measure of blame, and that the plantation had been formed at a heavier cost than was justifiable. One result of the investigation was that the Forest Department became henceforward associated with the Collector in the management of the plantations, and the idea of re-appointing a Superintendent in the position of independence and responsibility of Mr. McIvor was abandoned. This divided management was continued till 1883, when Mr. Lawson, took charge of the Plantations."

On which we have to remark that it is most unfair to charge the whole cost of the Quinologist's Department against the cost of the febrifuge. To the analyses and reports of Mr. Broughton all cinchona growers were much indebted, and there can be little doubt that the contemptuous tone of the report referred to, drove an able and sensitive man away from India.

THE WORLD'S EXPOSITION AT NEW ORLEANS.

(From the *Times Democrat*, Jan. 14th.)

Central America has made great efforts in all directions, her five republics constituting her vast domain, of Guatemala, the principal one; Salvador, Honduras, Nicaragua and Costa Rica vying with each other in all the departments of agriculture. The

REBUBLIC OF GUATEMALA

is one of considerable importance, not only for its agricultural resources but its historical associations. Central America runs north of Panama and south of Mexico, and Guatemala lies between the parallels of 16° and 18° north latitude, which is directly within the tropic belt and all agriculture is of the tropical order, Mr. W. J. Forsyth is the commissioner to the World's Exposition.

The government is composed of a Senate and House of Representatives, similar to that of the United States. The President is elected by the people. Gen. Barrios, who is now the Chief Magistrate of the country, has been its ruler for eight years, and has during that period inaugurated and consummated many reforms and advanced the condition of his people in every respect. He has established schools and colleges for their education, and has endeavored in every way to promote the interests of his country and the welfare of his people.

The City of Guatemala is connected by railway with the port of San Jose, on the Pacific slope. A railroad also connects the port of Champerico with Retalhuleu. Both of these towns are immediately joining the coffee districts of the Pacific slope. The whole country enjoys perfect telegraphic and postal communications. The City of Guatemala has a population of 66,000, and is the largest city in Central America. The elevation is 4,800 feet above the sea, giving a climate that is pleasantly cool the year round.

THE SHIPMENT OF COFFEE

amounts to nearly 400,000 quentals, or 40,000,000 pounds per annum. The two estates of El Parvenir and Los Mercerdes are among the largest in the world. The first is the property of the President, and when all the crop is in full bearing will yield 30,000 quentals. or 3,000,000 pounds per annum. Los Mercerdes, situated in the Costa Cuca District, is one of the largest and most profitable.

In Ceylon, in Southern India, which is the third largest coffee producing country in the world, and in which Mr. Forsyth spent six years, there are no plantations approaching in size or quantity of growth those of Guatemala.

Mr. Forsyth is an expert tropical agriculturalist, and is intimate with the coffee in Java and the Fiji Island, and is satisfied that nowhere are the conditions for its cultivation more suitable than in Guatemala. The elevation is from 3,000 to 5,000 feet, with an annual rainfall of from 100 to 120 inches, and a soil of a deep chocolate loam.

Most of the coffee finds a market in London, where it comes in close competition with that of Ceylon and Java. The producers are anxious to establish a large trade with America as it is nearer home and less liable to the damages of sea transportation. Coffee is a sensitive bean to outside influences, and will absorb the aroma of hides or other articles stowed in its vicinity. It commands a higher price in the London mart, which has been another cause of shipping it there.

THE SUGAR PRODUCTION

of Guatemala is also enormous. It is, in fact, one of the countries called the home of sugar. All the conditions of the country are favorable to the growth of cane. It is now

cultivated at altitudes ranging from 800 to 5,000 feet. On the Pantalion estate, the property of Mr. Herera, the first crop of cane was planted 23 years ago, and they have been cutting from the original stool yearly ever since, never once having to replant. This is in marked contrast to the care and replanting required by the cane in other portions of the world. The first few years of the cutting the cane was large and of less density, but of late years, although of a smaller growth, is much richer in saccharine matter. There are numerous other estates belonging to Don Jose Maria Samayoa which also produce valuable and luxuriant crops.

A few months ago Mr. Forsyth went on an expedition through to the Atlantic coast, exploring the Sarstoon and the western boundary of British Honduras, and on through to Lake Yzabal. This section had never before been visited by white men. He there, in that unknown region, discovered unlimited acres of land eminently suitable for the cultivation of sugar and all other lowcountry products grown within the belt of the tropics.

PLANTATION LABOR

is supplied by the Indians. These Indians seem to be an entirely distinct type from the races of North America. They are a peaceful, peaceable, law-abiding, hard-working and industrious race. They form the largest portion of the inhabitants of Guatemala. The whole of the Altas or uplands are broken up and cultivated by these people, who raise corn, wheat, barley, rice, peas, oats, and all the cereals indigenous to the tropical zones. During crop times on the coffee estates cash advances are made to them through the alcalda or mayor resident in their villages, and they, on going to work on the plantations, repay the money by labour at the rate of eighteen to twenty-five cents per day. They perform excellent labour and are considered equal to the Malabar cooly of South India, not only for the light work of the plantation, but heavy labour as well.

THEIR COMMUNAL LAWS

are singular and strictly enforced. In the land connected with their villages all have an equal right; there is no allowed proprietorship. Each one has an equal interest. To such an extent is this carried out that no one is permitted to grow other than annual plants. All cereals are classed as annuals; so is the banana tree. Coffee is not allowed. The reason for this regulation is that the planting of other than annuals would establish an ownership from year to year and would eventually lead to the disorganization of their communal system of government. A large majority of these Indians speak only their own tongue, of which there are, however, several languages. As soon as the coffee crops of the plantation owners are picked the Indians return to their homes among the Altas and pursue their avocations of agriculture. The

CULTIVATION OF CINCHONA

is another of the principal high country industries of Guatemala. There are now in extended nurseries throughout the Pacific slope and the Atlantic coast about 3,000,000 plants of the following varieties: Officinalis, condaminea, succirubra, robusta, pubescens and the calisaya. These nurseries are all in a remarkably fine and flourishing condition.

Mr. Forsyth, having entered into negotiation with the Barrios Government to introduce the cultivation of cinchona, and having contracted for 5,000,000 plants, proceeded to Madras, South India, to procure perfectly ripe and fresh seed, which are absolutely necessary to success.

This was the largest quantity that ever crossed the ocean at one time. The number and variety named above are the result of this shipment.

He also brought over Indian wardian cases of cardamom, tea, Pará rubber, cloves, nutmegs and other tropical plants. The cinchona plants are intended to be delivered to all the planters free of all charges. They will be planted on the coffee plantations as an anxiliary to the cultivation of coffee.

COCA (CUCA) AND COCAINE; TEA AND FIBRES IN CEYLON.

The medical journals and even some of the London dailies have lately had a good deal to say about Cocaine, the new drug containing the active principle of coca leaves, and its successful employment in deadening pain. There can be no doubt, that it will gradually come into general use for delicate operations on the eye and throat and it is also said to be good for neuralgia, but it is obvious that the demand thus created for coca leaves can never assume such proportions as to make them an important article of commerce, at any rate in Europe so as to encourage the cultivation of the plant to any great extent. There is, I fear, no adequate ground for the following sanguine anticipations indulged in by the editor of a monthly scientific journal with regard to the influence coca may exercise on the future prosperity of Ceylon. He writes:—"It may be remarked that this *Erythroxylon* is easily grown, and might well be introduced upon a commercial scale in Australia, India, and other British Colonies, with manifold advantages, both pharmaceutical and financial. Many parts of the Island of Ceylon are especially well adapted for growing coca, and probably this plant might be the means of restoring to many estates there much of the prosperity of former days. With the present great and increasing demand—which there seems no valid reason for believing to be a temporary one only—well-conducted *cocals* should yield dividends such as none of the much-vaunted cattle ranches can hope to attain, while the initial expenses would be far less, and the incidental risks comparatively insignificant." In Bolivia, Peru, and other parts of the South American continent the coca pouch is as indispensable a companion to the native as the betel bag to the Sinhalese and the local consumption must be enormous but there is nothing to show that the supply falls short of the demand and as it is not in the least likely that the natives of Ceylon and India will take to chewing coca or Europeans to drinking coca tea, though speaking from personal experience I can testify to its excellent qualities as a restorative of exhausted nature. There is small chance indeed that the misfortunes of Ceylon planters will ever be retrieved by coca.

Happily, however, Ceylon can confidently anticipate a gradual revival of something like her former prosperity by the extension of tea cultivation, though here again I feel bound to add a qualifying remark *apropós* of the exaggerated misleading statements often appearing in the home papers. These convey the impression to the uninitiated that the new product has already taken the place of the old, whereas a glance at the export returns of today compared with those of ten years ago suffices to shew what a vast amount of leeway has yet to be made up. Moreover, it must not be forgotten when forecasting the future that as the shipments of Ceylon tea to this market increase, so will the struggle for existence between it and its rivals, the Indian and China leaf, and eventually it will be a case of the survival of the fittest. Present appearances point conclusively to the opinion that Ceylon will hold her own because she possesses natural advantages over India at least, but in the meanwhile growers must be prepared for the inevitable result of competition in production, namely lower prices paid by consumers. Amongst the arrangements now in progress for extending the tea industry, I hear of the purchase for £2,000 of Messrs. Matheson's Ivanhoe estate in Ambagamuwa, consisting of 200 acres of abandoned coffee land, which I am told is very suitable for tea and this will be at once substituted for the old product. Under the circumstances £10 an acre must be considered a bargain as I suppose it is well roaded and has all the necessary buildings.

The directors of the General Fibre Company are naturally very pleased at the results of the trials with fibre cleaning machinery at Calcutta, by which the success of Smith's patent was officially recognized. The money prize was in itself insignificant, only R2,000, but the publicity given to the proceedings in the newspapers and in the Government report which I see you quoted in the last *Overland Observer*, has served the purpose of a splendid advertisement and several paragraphs on the subject have appeared in the home papers—indeed *The Times* had quite a long account of the exhibition the other day. Mr. Death, having demon-

strated the capabilities of the machine in the jute growing districts is now making his way home by way of South India and perhaps Ceylon, calling especially at the Glen Rock Company's estate in order to put the machines Mr. Minchin has set up there into proper working order. It is now estimated that a single machine ought to clean 30 cwt. of rhea stems, 5 tons of aloe leaves or plantain stems in a day and with even a three or four per cent outturn this would do very well. By the way, I hear that the Johore Rhea Company in which Mr. Edwin Watson is largely interested as vender of the land and local manager, is ready to be brought out very shortly, considerable support having been promised by Lancashire manufacturers since Mr. Watson's experiments proved the suitability of Johore soil and climate for the plant. This Company will work the Favier steaming process of decortication and the "ribands" will be dried by artificial heat immediately after being stripped off the stems.—*A London Cor.*

VICE-CHAIRMAN OF THE COLOMBO CHAMBER OF COMMERCE ON PLANTING PROSPERITY IN CEYLON.

(*March 12th.*)

Some of our heads of export I am sorry to say show some decrease on last year, but others again a very large increase. Coffee, which has hitherto been our main staple—I am taking the figures up to the 5th of this month, which will perhaps give us a better idea—coffee is 10,000 cwts. behind; we have only shipped 143,000 cwts. against 153,000 to this date than if I confined myself to the last half year—last year. Cinchona, on the other hand, I am glad to say, shows an increase of 1½ million pounds on the shipments of last year. We have now shipped 4 million pounds against only 2½ million lb. at this date last year. Tea also has practically doubled itself. We have shipped 828,000 lb. against only 476,000 last year, showing an increase of 350,000 lb. Cardamoms also show a large increase, practically double last year. We have shipped to this date—that is the 5th March—67,000 lb. against only 37,000 lb. last year, showing an increase of 30,000 lb. Cocoa, on the other hand, shows I am sorry to say, a very large decrease. We have shipped only 1,800 cwts. against 4,300 at the same date last year, a decrease of 2,500 cwts. The railway returns show that we are much about the same on the whole; the items which we notice in the Chamber circular amount to 36,000 tons and it was practically the same amount last year. Our prices are scarcely so good just now as they were twelve months ago. I think that is not difficult to account for when we take into consideration the political disturbances there have lately been. Besides this, the interruption to the telegraph line is a great hindrance, uncertainty has almost been worse than knowing the worst, but still I think we have not much to complain of in the matter of prices. Tea in the home market is continually gaining ground and showing that it is well appreciated. It is only a question of time when its consumption will become very largely extended. I wish I could speak more favourably as regards our prospects for the coming year. The weather so far has been very favourable, but on the other hand as regards coffee it is generally reported that the wood is not in a very good condition for blossoming and there has rather been an absence of blossoms of any kind and it is now getting late in the season. Still, we may have something better to report later on. Many people at home are under the impression that cinchona will collapse all at once in Ceylon. I think we are experiencing the reverse of this, as the returns I have quoted will show. I think, moreover, those who travel upcountry will find there are a good many roots still there and they will very soon show up again above the ground. There has been a good deal of coppicing going on lately, still our exports I think under that head will continue for some time to come. The death-rate does not seem to be nearly so large now as it was some time ago. Cocoa has evidently felt the continuance of drought, and I think the expectations for next year are rather disappointing on this ground. Cardamoms are still coming in in large quantities and will continue. A large acreage has been planted up and the exports under that head will show I think, at all events, no decrease for some time to come. Our great promise in the future however lies in our new product tea. I think it is to this to which we must look to restore prosperity to the country, if it is to be done at all. Experience has shown that it will practically grow everywhere where coffee used to grow, and it will also grow where coffee would not grow. We have therefore a very large acreage which we can go upon. I think, too, that we shall be able to compete with any other country and if tea pays anywhere it will pay in Ceylon. Our climate is very suitable, we do not have long droughts, we have a plentiful labour supply close at hand and everything seems to be in our favour. It may be that blight will come as it did with coffee, but we do not fear that to the same extent as we did with coffee. Coffee was confined to one crop a year and if that was lost all was lost for the season. With tea we have several flushes; if blight comes we can cut it down and we have several chances throughout the year. I will give you a few figures to show my ground for thinking that tea will restore prosperity to us. I find in *Ferguson's Directory* that 250,000 to 300,000 acres was calculated to be the area under coffee in late years. Well, I find that our Chairman, in replying to the Governor on the subject of the Northern Arm, estimates 150,000 acres as the probable area in tea a few years hence. This seems to me very much under the mark, but of course it is possible that for various reasons the whole available acreage may not get planted up so quickly as we would like. Well, taking only 150,000 acres, and calculating 350 lb. of tea per acre—I think that will be allowed to be a very moderate estimate, many put it higher, but for the subject of this calculation I think that will be sufficient. That gives us a total yield of 52,500,000 lb. of tea for the whole island for one year. If we value this at 1s. per lb.—which I think is also as low as we can put it—that will give us a total value of £2,625,000. Well, if we compare this with our former staple, coffee, in our best years 800,000 cwts. was about all we could produce for a series of years. If we value this at £3 a cwt. we get a total value of only £2,400,000, as against, as I said, for tea £2,625,000. The acreage I have taken for tea can of course be very largely extended if we find means and appliances for the purpose.

MR. GIBBS AND THE NEW TYPE GIBBS & BARRY TEA-DRIER

are very pleasantly discussed in the report of a "Commissioner" to the *Home and Colonial Mail*. Mr. Gibbs of Chilwell Park is described by this writer as an

encyclopædic genius, at once a poet of very high merit; an inventor who has done more for the agriculture of his country, in the way of saving harvests in bad seasons, than any other man; a philanthropist in the motives prompting his labours; and a hospitable genial English squire of the old school withal. Of his many and excellent poems, it is not here the place to speak, save in passing, and as calling attention to that rare combination of what are usually deemed incompatible gifts, those of true poetic inspiration, practical research, and perseveringly sustained effort—for a quarter of a century in this case on a problem which required mechanical skill and constructive talents in its solution.

The poem specifically mentioned is "Harold Erle" described as "a master-piece of perfect feeling and true poetic inspiration." We are told that

For the best part of a life of patient effort, during which he had many prejudices to combat and remove, Mr. Gibbs has devoted himself, and spent quite a fortune in inventing and popularizing appliances for saving harvests and "conditioning" grain, with the object, to him far superior to all pecuniary remuneration, of benefiting his country. For an essay on "Harvesting Corn in Wet Weather," he obtained the large gold medal and fifty guineas from the Society of Arts, and for an essay on almost the same subject received the large gold medal of the Highland and Agricultural Society of Scotland. His appliances are now known all over the world, and are the means of saving hundreds of thousands of pounds, and when they are as well known as they deserve to be, will probably save millions. Even in New Zealand, where the damp grain was so frequently harvested, it is being dried in his machines at the seaports, so that it remains sound and good wheat during the long voyage to this country. His hay-maker, for drying and saving wet hay, opened a prospect of saving millions of acres of meadow and other hay, which are damaged or almost destroyed every year by wet weather and its adoption by agriculturists, was proceeding rapidly when the rage for silos began. A vast proportion of the hay crop which will never be converted into silage is still left to the sad waste of the weather; but the Gibbs principle of desiccation by direct instead of intermediate application of the products of combustion has been found so effective that it is very largely used for a variety of purposes.

But to come to *the* object of my visit, the "Gibbs and Barry" tea dryer, this is an example of the adaptation of an agricultural invention to uses not contemplated at first. It is a case of talent directed into an unexpected channel by the technical knowledge of another person. The dryer which had been constructed to save wet harvests and "condition" grain, thanks to Mr. Barry's ready perception of its suitability, has been found an excellent appliance for drying tea. Mr. Barry deserves great credit for the perseverance with which for three years he carried out carefully conducted experiments, both in Calcutta, Cachar, and Assam, to test the Gibbs' principle as applied to tea, and to discover the form of air-duct most suited for the special purpose of tea-drying. He was the first to succeed in finding a practical method for drying tea by the direct application of the fumes of coke.

Several radical improvements in the construction of these dryers having lately been introduced, constituting a completely new type of dryer, it was my object to report upon these improvements, as most people interested in the matter are already familiar with the original "Gibbs and Barry" Dryer. Presuming upon this general acquaintance with the original type, it becomes easy to explain the improvements. These consist, first, in dispensing with the heavy undercarriage of iron girders, thereby reducing the weight by about a ton, and materially reducing the cost of the machine, as well as the freight and inland transit charges. The cylinders are now supported on specially formed brackets at each end, and instead of depending for their movement upon friction runners, as hitherto, they are driven direct from the fan or countershaft, by bevels and spur-gearing, which is certainly much more powerful, and more regular and accurate in its action than the friction-gear. At the same time the elevating and depressing arrangement is also much simplified and rendered sufficiently easy of action for one man to work instead of two. By far the most important result of this new mode of supporting and actuating the cylinder is that it gives the greatest facility for increasing the length of the machine to any extent that may be desired. The ease and economy with which this may be effected is obvious at a glance. For example, supposing one or more of the machines of the present average length are set up in a factory and it is found desirable to increase the out-turn of dry tea as more and more land is taken into cultivation or comes into bearing. A 6, 9, 12, or 18ft. length of cylinder and corresponding length of air-duct can be sent out all ready to attach to the existing machine. To do this, only one of the end supports or brackets need be moved; the cylinder is then taken apart in the middle by merely unscrewing the bolts, and the additional length is then inserted between the two lengths and bolted to them. The whole readjustment can be carried out in a few hours and the elongated machine set to work again without any derangement of the gear, driving-bands, furnace, or fan. In order to get the fullest additional drying power out of these lengthened cylinders, the fan is driven at a higher speed, proportional to the increased length. It is satisfactory to see that these important advantages are obtained without the slightest variation in the essential principle of these dryers. There is the same cylinder and air-duct, the same arrangement of shelves and louvres, the same fan, and therefore precisely the same mode of using and working the machine which has now been so long tried and so widely approved. Thus, instead of having to master all the details, difficulties, and defects of a new form of machine, the foregone experience of the managers and their subordinates remains as available as ever, without the worry of having to learn a new system, and without the waste of spoilt tea whilst so learning. Regarding the philosophy of drying, in the first simple forms of *choulahs*, floors or flat plates, it is of course well understood that the thinner the layer, the higher the heat; and the greater the current of air, the quicker will be the process; but thin layers involve large surfaces and a great extent of roofing over them, whereas if a floor be rolled into the form of a cylinder the space occupied is reduced by two-thirds at once by that very simple change of form. Then, as to heat, if the layer, however thin, be left unmoved it will not bear a high temperature without scorching. Whereas, if lifted up and poured out slowly and continuously in a stream of hot air, it has been proved to bear three times the heat that would otherwise utterly destroy it, and this is exactly what the interior shelves of the cylinder effect. At the same time this thorough separation of all the wet lumps of clotted tea together with the controllable retarding action of the cylinder, admits of the free use of very large volumes of air without any practical inconvenience. The three chief conditions for safe, rapid and thorough drying are excellently combined in this powerful, yet simple, machine:—

1st.—A gentle and gradual separation of the rolled tea, so that every leaf gets its full share of the drying power.

2nd.—A perfect distribution, through the whole length of the cylinder of immense volumes of air at a high temperature.

3rd.—A slow automatic movement of the tea from one end of the machine to the other, which movement can be graduated to the greatest nicety by merely the turn of a screw so as to obtain the exact point of dryness with the least possible trouble, labour, or risk.

All this will be interesting, especially to those in Ceylon who are growing tea on a large scale. As we recently stated, the largest tea company in the world, the Assam Company, have ordered six of the improved Gibbs & Barry machines, so that authentic information as to their performance will speedily be available. We do not know if the improved Gibbs & Barry machine finishes off the leaf, instead of only partially firing it at a great heat, but we suppose it will be capable of both processes.

NETHERLANDS INDIA.

BOTANICAL LABORATORY—TOBACCO.

(*Translated for the "Straits Times."*)

Mr. Treub, Government botanist, in consequence of the installation of a simple botanical laboratory at Buitenzorg in the building within the Government Gardens, has, by means of a circular in French, invited European botanists to come and spend half a year in the Gardens studying the tropical flora. He describes the studying premises as fitted with four tables fronting four windows provided with the necessary chemical re-agents and appliances, there being also facilities for

buying herbarium paper and alcohol at Buitenzorg, but visitors from Europe must bring bottles and btubes with them. Mr. Treub estimates that the whole voyage, along with the residence in the Gardens, need not cost more than 5,000 francs, and expresses the hope that learned societies in Europe may make it easy for such of their members as may feel inclined to do so, to carry out the idea.

Tobacco cultivation in Java.—We have received by the mail the yearly market report on the tobacco trade drawn up by Mr. Lieftinck, a broker at Amsterdam. It appears therefrom that in 1884 28½ millions of pounds of tobacco were sold by Amsterdam and Retterdam import houses, that is half a million more than in the previous year. Of this quantity, 19 millions were from Sumatra, 6½ millions from Java, and 3 millions from other countries. While the total yield of Sumatra tobacco had always been on the increase there became manifest in 1884 the usual phenomnon of a falling off in quantity as regard Deli and Langkat. The Java tobacco brought a considerably higher prices, the difference between it and that realized the previous year being 72%. The compiler of the report hence asserts, which may be reaffirmed on better grounds than before, that should Java be favoured with abundant crops there is every reason for expecting that those who continue to run the risk of carrying on tobacco cultivation will not be disappointed in their hopes of satisfactory results. Among the residencies in Java which have been given up by tobacco planters is Rembang, where there is now no longer any permanently worked estates.

We learn that in North Borneo on the Island of Bangie, a new tobacco estate has been started under the management of a co-partnership styled the German North Borneo Company. The director of this undertaking is Mr. A. Becker, head partner of the Hotel de l'Europe at Singapore. The analysis of soil shows it to be a promising one, there being every chance of the tobacco yield proving heavier than in Deli. The Company is domiciled at Hamburg and has command over a very large capital.

Samarang, 9th February.—The coffee leaf disease, so we are informed from several estates, begins to show itself more and more. It is not improbable that the wet weather has had some influence in bringing this disagreeable phenomenon about. Leaf disease seems unable to stand drought.

Gas-lime for Gardens.—Gas-lime, if applied to that extent, will prove a remedy far worse than the disease. I quite agree that it would banish the slugs, &c.; they would not appear again for some time either, where there was nothing for them to eat.—W. H. Divers, Ketton Hall. —*Gardeners' Chronicle.*

Indian Teas in Melbourne.—The following are a few of the best sales of Syndicate Teas on 26th February last:—

54 chests Darjeeling Pekoe: Very well made even wiry brownish leaf. Rich delicate fruity Darjeeling flavor ... ... Is 3½d

30 half-chests Kangra Val. Orange Pekoe: Reddish wiry evenly made leaf few tips. Malty rich delicate fruity Pekoe flaver ... ... Is 2¾d

30 chests Cachar Pekoe: Handsome well made evenly twisted leaf. Pungent delicate flavor... ... Is 3¾d

32 chests Darjeeling Pekoe: Well made blackish evenly twisted leaf. Fine fruity Darjeeling flavor ... Is 5¼d

8 chests Darjeeling Pekoe: Well made even brownish leaf. Very flavory fine full Darjeeling liquor ... ... Is 3¾d

19 half-chests Cachar Pekoe: Very handsome wiry even browuish leaf. Very rich full malty delicate infusion ... ... Is 5¾d

25 half-chests Cachar Pekoe: Fairly well made even black leaf. Very superior full malty ripe liquer Is 3¾d

GAS-LIME FOR WEEDS.

That the earth is mother of the weeds, but only step mother to many of the plants cultivated on it, is a not inapt way of accounting for the healthy and abundant crops of weeds. The weeds are always with us, and only by watchfulness and much labour can they be kept under. It may be safely said that there is no work in which there is worse economy than in letting weeding run unattended to, want of the proverbial stitch in time causing need for nine is much more than realized in the matter of weeds if unchecked. Of the many plants that come under the category of weeds, when growing where they are not wanted, grass on walks, pebble pavement, and little used roads, such as many carriage drives through parks or other grounds, when the traffic, as it often happens, is not sufficient to keep the surface clean, becomes the most troublesome of weeds, for on roads of this kind, even where diligently weeded before the seeds have time to fall, there is an inexhaustible supply always coming from the land adjoining that makes it an endless task, only varied by the different means in different cases resorted to to destroy them. Those who have had anything to do with such work need not be told that handweeding of this kind is slow work; the use of hoe and rake is objectionable; salting, either with the dry article, or in the shape of scalding brine, is costly in labour and material; whilst the use of diluted arsenic or vitriol, in addition to the expense in material and labour, is objectionable in different ways. Where gas-lime can be had there is nothing that will be found more effectual, and, in most cases, economical, scattered on the surface in the way that salt is applied, and allowed to remain for about three weeks. It will not only destroy all the grass and weeds, but will also kill any seeds that may be present but not yet vegetated, in addition to which it will prevent any growing for a couple of years. After being allowed to remain long enough to kill the weeds the material may be swept up and used in the way of manure. It is scarcely necessary to say that the lime is more powerful in its effect for the purpose under notice when fresh than if it has lain for some time after it comes from the gas-maker. There may be some objection to the use of gas-lime in the manner described on account of its powerful smell, but even in the vicinity of a dwelling there are often times when it can be applied without giving annoyance through this cause.—T. B.—*Gardeners' Chronicle.*

VEGETABLE CULTURE IN BERMUDA.

Consul Allen says that onions, potatoes, and tomatoes comprise almost the entire production of Bermuda, and give employment to the greater portion of the inhabitants, and the prosperity of the colony depends largely upon the success of the crop and the demands of the markets. In onion growing the seed used is grown in the Canary Islands, and is imported in the months of August and September; it is sown in the months of September, October, and November, thickly in beds, the ground having been heavily manured with stable manure two or three months before sowing. The white seed is sown first and produces the earliest crop, the shipment of which commences in March. When the plants are sufficiently large —about 6 to 8 inches high—they are transplanted into beds about 4 feet wide, the plants being set about 7 inches apart each way. The plants from the white seed are transplanted as soon as they are large enough, but those from the red seed are not usually transplanted until the beginning of January, and the ground requires to be only moderately manured. If transplanted too early, and the soil is too rich, the bulp is likely to split into several pieces and is worthless. After transplanting, the soil requires to be lightened once or twice, and the weeds removed before they mature. As soon as the top begins to fall, the onions are pulled and allowed to lie on the ground two or three days, when they are cut and packed in boxes of fifty pounds each and sent to market. All the onions are delivered at the port of shipment in boxes, ready for the market, and for the past two years the producer has been compelled by law to place his name or initials conspicuously on each package. It is estimated that a large profit on the outlay is realized, when the

crop is large and the market good, an acre of ground sometimes returning as much as £120 to £170. For the cultivation of potatoes the seed was formerly nearly all imported from the United States, but of late years has come largely from New Brunswick, Nova Scotia, and Prince Edward's Island. The ground for potatoes is usually ploughed or broken up with the spade and raked, the seed cut into pieces with one or two eyes, and planted by forcing into the ground with the fingers to the depth of about four inches, in rows about twenty inches apart, and about eight inches in the rows. From six to eight barrels of seed are used to the acre. When the plants are a little above the ground, the soil is lightened between the rows with a fork, and when about six inches high the earth from between the rows is hoed round the plants, only one hoeing being required. For growing tomatoes the seed is imported every year, and is sown about October, and transplanted in December, into rows about six feet apart, and the plants are put about four feet apart in the rows. As soon as transplanted, the ground round the plants is covered thickly with brush—chiefly the wild sage which grows over the hills—not only to protect from the wind, but to keep the fruit from the ground. The brush is usually raised once by running a stick under and lifting it enough to clear the soil of weeds, no other cultivation being required. Six or seven quarts of fruit from the hill is considered a fair crop. The fruit is rolled in paper and packed in boxes containing about seven quarts each. Consul Allen says that the price of land in Bermuda varies from £30 to £40 an acre, and in some cases not more than one-eighth is susceptible of cultivation. It is estimated that there is an annual export of 350,000 boxes of onions, the box containing about 50 lb., and of potatoes 45,000 barrels.—*Journal of the Society of Arts.*

INJURIOUS INSECTS IN 1884.

A very noteworthy report on the ravages of injurious insects during the period between the months of November, 1883, and December, 1884, together with the operations taken to checkmate them, has just been presented to the Royal Agricultural Society by Miss E. A. Ormerod, F.M.S., the consulting entomologist to the society. Some idea of the amount of observations now being made may be gathered from the fact that this lady during a portion of this time has received reports and letters to the number, on an average, of 25 per week. The points of communication have been in some degree regarding attacks on colonial produce, but mainly on crop attacks in England. There has been communication in a lesser degree from Scotland, and much more than in previous years from agriculturists in Ireland. Inquiries have been sent regarding "green fly" on cabbage and turnip and prevention of ravage of daddy-longlegs grubs, which have been very destructive among corn and other crops; also regarding the red maggot of the wheat-midge in corn, and the same and nearly allied species in seed (grown for sale) of meadow foxtail grass; likewise regarding thrips in wheat. Hop aphis has been well observed and reported from the letter part of March until September. Mangold maggot and the rare attack of the mangold and beet carrion beetle have been under notice, and onion maggot has been practically attended to. Turnips suffered badly in many places from surface caterpillars, the injury continuing up to the beginning of this month, and in a few places from attack to the leaves of the small but very destructive caterpillars of the diamond-back moth. Wire worm and turnip "fly," or "flea beetle," have been bad in various places, but little injury has been sent in regarding them; therefore it is hoped that the information published by the society has been found serviceable for reference. Communication has taken place regarding many other crop and fruit attacks, and some inquiry been made relatively to the water snail (*Limnæa truncatula*) in connexion with liver fluke. Sound and valuable information has been contributed regarding ox warble fly, and observations are being continued on a system which cannot fail to give most of the information still needed. * * * * *

With regard to prevention of attack it has been found by experiment on the acre of hop land at Stoke Edith-park, near Hereford, of which the use has been given by the courtesy of Lady Emily Foley, that various applications to the surface of the hop hills, about the time of dressing in spring, entirely prevented the appearance of wingless females or lice on the bines of these hills (though the others in the ground were infested) until the attack came on the wing at the end of May. Of these applications paraffin mixed with ashes or with earth, shoddy, or other dry material answered the best; the bines on the hills so treated were reported thriving throughout the season up to good bearing. Various methods of combining paraffin or other mineral oils with soft soap and water, so permanently that the mixture may be diluted without again separating into oil and water, are stated to have been found serviceable for destroying aphides in the experiments made under direction of some of the State entomologists of the United States of America, but from personal experiment it seems so difficult to find the exact strength suitable for killing the insect without risk to the plant that we should be afraid at present to advise this application to the hop leafage. As a watering or as a more convenient method of applying paraffin in the attacks for which it is now used (as of mangold fly, for instance) the plan of mixing is likely to be useful. Quassia has been acting well during the last season as an addition to the common soft-soap hop washes. Paris green was tried and failed to have any effect on the hop aphides. A method of hop washing by steam power has been introduced near Tunbridge Wells, which has as yet only been tried on a limited scale. So far it is stated to be successful, and to have the advantage of washing a much larger acreage at a lesser cost per day than can be done by the hand or horse engines.—London *Times.*

THE ORIGIN OF CULTIVATED PLANTS.

When Alexander von Humboldt wrote his 'Essays on the Geography of Plants,' in 1807, the origin or first home of the plants most useful to man, and which have accompanied him from the most remote times, was unknown. Half a century later, in 1855, so diligent had been the work in this field by European botanists, that the homes of the greater number had been discovered. *Facile princeps* in these researches was the swiss botanist, Alphonse de Candolle, and now, after another thirty years, this veteran gives us a full account* of our present state of knowledge on the subject. Of the two hundred and forty-seven species enumerated by M. de Candolle as being now cultivated for their utility to mankind, the native *habitat* remains still unknown of only nine, viz., two species of barley, *Hordeum hexastichon* and *vulgare*; spelt, *Triticum spelta*; the pea-nut, *Arachis hypogæa*; the clove, *Caryophyllus aromaticus*; the sweet potato, *Convolvulus Batatas*; the lubia, *Dolichos Lubia*; manioc, *Manihot utilissima*; and the kidney bean, *Phaseolus vulgaris.*

It is very remarkable how early civilized or half-civilized man seems to have discovered, in all countries, the plants most useful to him for food, raiment, or other purposes. Of those already referred to, more than half were certainly in cultivation in the Old World over two thousand years ago, or in the New World before its discovery by Europeans, and probably from very ancient date. Of the species brought into use in more recent times, the most important are those which have yielded valuable drugs or gum-resins, like the South American *Cinchonas* and the Australian *Eucalypti.* "Men have not discovered," says M. de Candolle, "and cultivated within the last two "thousand years a single species which can rival maize, "rice, the sweet potato, the potato, the bread-fruit, the "date, cereals, millets, sorghums, the banana, or soy. These "date from three, four, or five thousand years, perhaps "even in some cases six thousand years."

Equally noteworthy is the almost entire absence from some countries of indigenous cultivated plants. The vast territory of the United States yields, as nutritious plants worth cultivating, only the Jerusalem artichoke and various species of gourd. Australia and New Zealand may be said to have furnished nothing of value except the *Eucalyptus globulus*; those countries are entirely destitute of grasses

* 'Origin of Cultivated Plants.' By Alphonse de Candolle. London: Kegan Paul, Trench & Co. 1884. (International Scientific Series.)

or leguminous plants with edible seeds, and of cruciferous plants with fleshy roots.

Another class of plants is mentioned as having been observed but rarely in the wild state, probably occurring only occasionally, and now extinct or likely to become so, as indigenous plants. This class includes wheat, maize, the common bean, lentil, chick-pea, and tobacco. Their failure in the struggle for existence is due in all cases to their possessing seeds containing abundance of starch, and consequently affording an attractive food for birds, but having no power of passing through the alimentary canal unchanged. If dropped out of cultivation, they would probably entirely disappear. M. de Candolle has not observed in any of the species investigated the slightest indication of adaptation to cold. When the cultivation of a species, such as maize, flax, or tobacco, advances northwards, it is from the production of early varieties which can ripen their fruit during the short summer. Periods of more than four thousand or five thousand years appear to be required to produce a modification in a plant which will allow it to support a greater degree of cold.

These are a few of the general facts which M. de Candolle brings before us. The details in the case of particular species are full of interest. Thus he shows how the bitter orange we certainly introduced into Europe before the sweet orange, but both at comparatively recent dates, the introduction of the former being apparently one of the benefits conferred on Europe by the conquest of the south of Spain by the Moors. All the species of tobacco, with the exception of one from Australia, are stated to be natives of Southern America.—*Pharmaceutical Journal.*

MISS NORTH ON VEGETATION IN CHILI.

The following is an extract from a letter written by Miss North to Professor Allman, here published by permission of the writer. Miss North left this country last autumn with the view of studying the vegetation of the western side of the Andes, especially in the Chilian region, where she is now engaged in painting the characteristic features of that portion of the Andean flora, hoping thereby to fill up almost the only gap still remaining in her marvellous gallery at Kew. One of Miss North's special objects in visiting that part of the world was to find an opportunity of painting the Araucaria imbricata in its native haunts, She had not yet, however, reached the proper region of the Araucaria, which is at a considerable distance from her present quarters, but has made the necessary preparations for the journey, and hopes soon to get studies of this singular and characteristic form of Chilian vegetation.

Though reference to the Araucaria is thus necessarily omitted in her letter, Miss North's graphic account of the vegetation amidst which she is living will be read with no little pleasure by every one interested in the geographical distribution and physiognomy of plants, and in their significance as elements in the landscape.

"Apoquindo, Chili, Oct. 28, 1884.

"Dear Dr. Allman,—Again I am going to bestow on you the glories of a vegetable, too magnificent and unique to be appreciated by ordinary mortals. Last spring botanical journals told every one to go and see the Puya in the Cactus-house at Kew, and I made a hurried sketch in the midst of all my 'fixings' and vexations in the gallery. [A figure of P. cœrulea *alias* Whytei was given in our columns, October, 1, 1881.] I did not like to propose that such a precious plant should be taken into my room. Its relations here would not even own it! I have a flower of one leaning against the post of the verandah before me now, which is just as much as I can lift with difficulty. The flower-spike is over a yard long, its stalk 6 feet. It has sixty spikes, arranged screw fashion, round its stalk, each about a foot long, and round these are rosettes of flowers and some score of buds of the tenderest green or lemon colour. The great heads before the flowers come out are wrapped up in covers of white kid, tinted with salmon, getting darker as they fall aside and the lemon buds push themselves out, and the first flowers, which open round the base of the spikes near the stalk, are of the purest turquoise-blue; the new rosette which replaces them is darker, metallic-blue, and then all the others seem to get more and more green and faded the further they get from the central stalk, and more separate, with a background of brown bracts or leaves (the original white kid covers). Yesterday I rode and scrambled on foot far into the hills, and saw masses of these huge flowers. On one mass of silvery Pine-like leaves there were twenty-six flower-stalks, most of them brown heads of last year, with the seeds shaken out, and all growing on the steepest slopes, and having as companions giant Cacti, with a Loranthus parasite covering their sides, facing east or south; they are now covered with scarlet berries, which grow white when ripe, and are not bad to eat, tasting like Roses; the juice from the stalk of the white trumpet flower of the Cactus is also good. I am black and blue from the falls I have had on those steep banks, with no foothold but sliding stones and prickly bushes for hands to grasp as help, but it is worth some trouble to see such things. Every bush seems prickly or poisonous here, the 'Nettle,' a plant with red and yellow flowers (Blumenbachia) raises watery, blister-like burns, which last days on one's hands. When I see you, I shall ask you to tell me how and why it does it. I had a theory that it did not sting till the flowers had opened, but touched the buds once too often, and will not theorise in that way again. The common Acacia (much like the Dornboom or Baubul of Africa and India) is terribly thorny, yet seems quite a favourite place for birds to build nests in, and one clever weaver makes his home of the very thorns, lining the inside with the soft gold ball flowers. I tried in vain to get the nest to take home —I brought out only bleeding hands, but it is painted; and I hope to get the bird from Dr. Phillippi at the Museum. Another bird's nest with two eggs I found in a hollow dead Cactus pillar, made entirely of feathers, and one of the thorny sort wedged between two live Cacti. We went to a grand waterfall yesterday, the young landlord acting as my guide, and close under it I saw Darwin's Berberry. The tree, whose bark is used for soap, was growing in quantities there [Quillaia], with Ecremocarpus hanging from it, and the tiny scarlet Tropæolum all over the lower bushes; also a lovely pink flowering creeper, whose name I forget. The other flowers are very tiny; several Vetches of different colours, Oxalis, Lilies, scentless Heliotropes, Verbenas, yellow Forget-me-Not, yellow and Lemon Calceolarias, hanging from the rocks, and Maidenhair, which stands upright, not hanging.—Marianne North.—*Gardeners' Chronicle.*

CHINESE HORTICULTURE.

A Chinese kitchen garden contains almost all our vegetables, and many more besides. If they do not care to grow potatoes, except where there are Europeans to eat them, they grow the batata, which is sold boiled at every street corner. Of the water-lily, sacred to Buddha, they eat the sugary seeds; and also a sort of sago made from its root. "Water-chestnuts," too (eaten by the old lake dwellers in Switzerland), are largely grown. Every canal is full of floating islands of them; and the gathering must look like that picture in this year's Grosvenor of Athelney in Flood, where young and old are going about after the apples in boats. Instead of boats put tubs, each pushed with a bamboo pole by a yellow man or woman, and paint two or three upsets, for John Chinaman is full of fun, and those who have seen a water-chestnut harvesting say that everybody is on the broad grin, and accepts a ducking with the same good humour with which he gives one. They cultivate fungi, too, burying the rotten stump of a tree which bears harmless ones, and so ensuring a crop. One kind, the lin-chi, is one of the emblems of immortality. It gets as dry as those honey-combed fungi which they eat in mid-France, and "keeps good" for years. The bonzes use it as the foundation of their ambrosia, and picture their gods with lin-chi in their hands. The "five fruits" are peach (sign of love, because it blossoms in winter), apricot, plum, chestnut, and jujube. The wild apricot is valuable for the oil extracted from its kernels. The first came into use, say the Chinese botany books, in our fourteenth century. A good and wise physician lived in a district so poor that he scarcely ever got a fee; so, having found out the use of apricot oil, he said, "If you can't pay you must do this: Let every patient plant a

wild apricot on that bare hill to the east." Fifteen years went by; the hill was pretty well covered. "Now," said the good man, "I am growing old, and after me you will perhaps not be able to get your doctoring gratis. Let the village undertake to keep up this apricot-orchard that has cost you nothing. The oil will not only pay a doctor and buy as much medicine as you can want, but it will also do a good deal towards supporting your old men and your orphans." . . . Wax-trees and tallow-trees are invaluable to the Buddhists, who, of course, must burn no animal fat on their altars. There are half-a-dozen trees and plants which make better paper than the bamboo—what we call rice-paper, for instance, comes from the paper-mulberry. A Chinese nettle and a giant hibiscus make excellent rope; and the ramia has its leaves covered with threads just in the right state for spinning. When Virgil said, "The Seres comb from leaves a slender fleece," one used to fancy he was speaking of silk, confounding in fact the worm with the food it eats; but the latest idea is that some notion of the ramia and its produce had travelled as far as the Greek naturalists on whom Virgil relied. If any of your friends are homœopaths you will have heard plenty about rhus; one of the many kinds, the rhus vernix, makes, along with the elaeo-cocoa (added because its juice is fatal to insects), the famous lacquer. Great at dyeing, the Chinese have managed to find out vegetable mordants. Hair-dyeing they manage in a peculiar way; they drink their dye. A six months' course of some vegetable decoction is said to be infallible; and was regularly used, we are told, by the Christians to darken the hair of their European priests, that so they might escape detection. Nearly all their dyes are vegetable, the imperial yellow being got from the root of the curcuma; saffron and gardenia flowers, and mignonette, and all other yellow dyes being held unworthy of this great object. And now, to prove what has been said about their great skill in landscape gardening, let us say a word about the Pekin Summer Palace Park. Mr. Swinnoe and Sir Hope Grant both paint it in glowing colours—such a pleasure garden as Kublai Khan planned round his "wondrous dome, by Alp, the sacred river." "Twelve miles of pebbled paths leading through groves of magnificent round lakes into picturesque summer-houses; as you wandered along herds of deer would amble away from before you, tossing their antlered heads. Here a solitary building would rise fairy-like from a lake, reflected in the blue water on which it seemed to float. There a sloping path would carry you into the heart of a mysterious cavern leading out on to a grotto in the bossom of another lake. The variety of the picturesque was endless, and charming in the extreme. The resources of the designer appear to have been unending." And what the Emperor had in its fully glory round his summer palace every Chinaman who has made a little money tries to have on a small scale round his house. It is the gardens which, in the absence of many of our modes of sanitation, keep the dense populations of Chinese cities tolerably healthy, for trees are great absorbers of bad and diffusers of good gases. We have a great deal still to learn from them in the way of gardening, and it is no use crying down our climate—the climate of North China is a very harsh, ungenial one, far worse for both men and plants than ours. It is not the climate that is in fault, but the gardeners; ours do not put the heart and patience into their work that John Chinaman does into his.—*All the Year Round.*

QUEENSLAND SUGAR INDUSTRY AND THE LABOUR QUESTION.

EXTENT OF THE SUGAR INDUSTRY IN MACKAY.

From a gentleman who was one of the pioneers in sugar-planting in the Mackay district, and who is thoroughly conversant with the values of the plantation properties in this district, I have been informed that he would estimate the total value of the sugar estates, with the plants, buildings, and other accessories necessary to carrying on the business, together with the capital required to work them, at about £2,350,000. In addition to this there would be the money invested by small growers, who have their cane crushed at the central mills, and when to this is further added the capital invested in businesses in the town consequent upon the wants created by the establishment of the sugar industry in the neighbourhood, some idea may be gleaned of the very large monetary interest which is involved in the welfare and success of sugar-growing in Mackay.

With regard to the small growers in this district I may mention that in each case where I made inquiry coloured labour was employed by the farmer, the number of boys of course differing according to the extent of land under cultivation.

At a meeting of planters held in Mackay about the middle of July, it was stated that on the plantations alone the proportion of white to black labour was one white man to four kanakas; but if the whole population of the district dependent directly and indirectly upon the sugar industry were taken into consideration, then the proportions would be reversed in the ratio of two white men to every black man.

At this meeting the following resolutions, which express the views of the planters on the labour question, were passed:—

"That the sugar industry is one of great value to the country, affording, as it does, employment to many thousands of persons skilled in the agricultural, chemical, and mechanical arts; and that the character of our climate and coast land is peculiarly favourable to the prosecution and extension of the industry."

"That after undergoing the many privations and trials incidental to establishing any new industry, in addition to those inseparable from the settlement of a new country, the sugar-makers of Northern Queensland have, after many failures and vicissitudes extending over 20 years, succeeded in perfecting the production of cane sugar in this colony, and in acquiring in the hard school of experience a knowledge of the industry which will, if properly applied, be found valuable to themselves and to the colony."

"That owing to the extensive production of beet sugar, caused principally by the low price of wheat, which is almost certain to continue, the price of cane sugar has been so lowered that it can only be produced profitably in those countries commanding a sufficient and reliable supply of low-priced labour."

"That such a supply of low-priced labour is procurable in this country only from British India, the supply from Polynesian labour having failed to meet the requirements of the industry, and offering no possibility of extension."

"That the whole material interests of the population of the Queensland coast, north of Cape Palmerston are bound up with, and dependent on the successful prosecuting of the sugar industry; and that, should that industry fail, an almost general exodus from Queensland may be expected to take place of all persons skilled in the sugar industry and its allied trades to those neighbouring colonies which have wisely made a proper provision for the supply of labour necessary for the successful prosecution of the industry.

"That to enable the sugar industry in Queensland to continue to exist, it is necessary that the governing bodies of the colony should make such laws and regulations as will at once admit of the immigration of natives of India to serve as indentured labourers for the cultivation of tropical products and the preparation of same for market only.

"That the danger of Chinese settlement unless met by competition with other law-priced labor be pointed out."

As the argument on the other side, I will quote from the speech of a settler in the district who was opposed in view to those who represented the planters' interest. He said the question was whether they wanted coolies or white men in the colony. At the present time there were hundreds of white men walking through the country who could not get work, and it was proposed to add to this difficulty by importing coolie labour. He would like to see capital more generally diffused than it was. It was at present only in the hands of the few. If this capital were more diffused through the country, a greater number of white people would be enabled to obtain a livelihood. His own idea was that sugar could be raised in that district by white labour alone. He himself had helped with Mr. Spiller to put in the first cane planted in the district. At that time it was said sugar could not be grown by white men in tropical Queensland, but Mr. Spiller had

stated that such an assertion was "all bosh." He (the speaker) attended the meeting as a working man, and he believed that it lay with the planters themselves to settle this question. He thought that if they were to look about they would find on their plantations some good, industrious white men, say ploughmen, to whom they might rent a certain number of acres of land at a nominal rental, and, supplying them with the necessary implements, get them to cultivate sugar for the mills. He believed such a plan would succeed. He would very much like to see more of his countrymen, who were almost starving in the old country, come out to this new land and obtain a decent livelihood.—*Sydney Mail.*

BATOUM TEA.

A few months ago, Mr. C. B. Allen presented to the Museum, along with several Turkish drugs, a specimen of a tea, closely resembling in appearance Chinese tea, but having a somewhat sweet and less astringent taste. With the specimen was sent a dried specimen of the plant, in fruit only. This was identified for me by Mr. J. G. Baker, of Kew, as *Vaccinium Arctostaphylos*, L.

The following information concerning it has been furnished to me by Mr. Allen :—

"The plant yielding the tea grows on the sides of streams and of hedges, and on uncultivated ground, in Lazistan, in Adjora, Kroum and about Trebizond, but is not found beyond the mountains of Gummo hame. It was never applied to any useful purpose until the year 1877, when an individual who had some knowledge of the mode of preparing tea collected the leaves and manufactured them into tea. The article that he produced had a very pronounced odour, analogous to that of China tea, but it possessed also an acridity disliked by connoisseurs; notwithstanding this, however, he put up for sale as tea a certain quantity, which was bought up by tea dealers and sent into Persia, where it passed successfully as tea. Seeing this the inhabitants of the neighbourhood of Kroum and Lazistan soon followed the example set them, and a year after the first sale as many as two thousand cases of the Batoum or Lazistan tea were sold at Trebizond, mixed with good Chinese tea, and sent to Persia. When this came to be known to the Turkish Government, the director of the forest department imposed a tax of twenty per cent on this product, and notwithstanding the representations of the then governor of Trebizond, the impost was not removed, and as a consequence the collection was abandoned." Mr. Dickson, the gentleman who forwarded the specimen to Mr. Allen, further remarks:—"The leaves are gathered in July and August, and as the plant probably flowers in May, that accounts for my being only able to send the specimen of the plant in fruit. I believe this tea plant must grow all along the Taurus range, for it is found at Batoum, Trebizond, Karamoussal and Broussa. The tea varies in quality, and when carefully prepared it is very nice and palatable, but when carelessly prepared it affords a dirty disagreeable beverage."

The production of this tea is noticed in the Blue books for 1879 (Commercial, No. 19. C. 2331), p. 1023, where it is remarked that the reduction of the forest dues would enable this tea to compete strongly with teas imported from Great Britain. A specimen of the same tea prepared at Amassia was exhibited by Mr. W. T. Thiselton Dyer at the meeting of the Linnean Society on November 6, under the name of Trebizond tea, as well as several dried specimens of the plant in flower, one of which has since been presented to the Museum of this Society. It would seem, therefore, as if the tax had been removed and the tea again manufactured. The leaf is much thinner than the true tea leaf, and could, I think, be easily distinguished by a botanist from the true tea leaf when soaked in water, should the tea ever come into use in this country as an adulterant of cheap teas.—*Pharmaceutical Journal.*

INDIAN TIMBER.

Public attention in England is being directed to the value of India as a timber exporting country. Just before the last mail left Mr. D. L. Simmonds, who has devoted much attention to this important branch of industry, read a paper before the Society of Arts on the "Past, Present and Future sources of the Timber Supplies of Great Britain" :—

In the course of his remarks Mr. Simmonds stated that at present the exports of wood from this country are comparatively small in amount, and would, indeed, scarcely deserve mention, but for the large quantity of teak, on an average of 55,000 tons, sent to the United Kingdom from Burma and other coasts of India. It is believed that no country in the world is such a large importer of wood as England, but only a very small proportion of her supplies are obtained from British possessions. Twenty-five years ago the United Kingdom received about 3,400,000 loads of foreign and clonial wood of every description; in 1883 upwards of 6,500,000 loads were imported. Of this only 1,529,000 loads were supplied by India and the Colonies. The total value of forest products imported by England last year was £31,518,919, but India's share of this enormous sum was only about half a million sterling. Mr. Simmonds, however, points out that until recent years little attention was given by the Government to the due preservation of the vast forests of India, and he looks forward to a large increase of the exports from this country when the woody tracts are more easily reached by rivers and roads. He points out that large shipments of the toon wood of India (*Cedrela toona*) might be profitably made, if it can be delivered at Chittagong or some Burmese port, but exports from the forests of Northern India are out of the question. There is, it seems, an unlimited demand for sandalwood in Europe, but the Bombay dealers apparently find it more profitable to ship it to China, whence it goes to Europe in the shape of ornamental work of different kinds. Bombay blackwood furniture is not greatly prized in æsthetic households at home, and expect among Anglo-Indians, there is, we believe, little demand for it. According to Mr. Simmonds, Indian blackwood generally (*Dalbergia Latifolia*) is in slight request, and what is imported is all used for furniture. In the discussion which followed the reading of the paper several gentlemen connected with Australia descanted on the excellence of the wood produced there, one of them going so far as to say that jarrah is far superior to teak. This is a question that may very well be left to the decision of experts; but it is a pity that there was nobody present to put in a good word for our Indian teak. Jarrah may be as valuable as the Australians make out, but if it is so greatly superior to teak, why is it ignored in England as a shipbuilding wood? In Western Australia almost everything is made of jarrah, and the people of that colony cannot understand why there should be such a great prejudice among the English shipbuilders and others against a wood which, if not quite everlasting, is nevertheless said to defy all known forms of decay, and is untouched by white ants and all other insects. Last year some seven hundred tons of jarrah were imported into India, but hitherto apparently none whatever has gone to England, in spite of the efforts of the colonists to obtain a demand for it in the old country. It will doubtless be a long time before teak is superseded in the home market by its Australian rival, but there should be a large trade for both.—*Pioneer.* [The great point in favour of teak, we suppose, is its possession of a fragrant oil which renders it impermeable to the attacks of insects. It neither splits nor warps too.—Ed.]

WHY DO OUR WOODS NOT PAY?

Because we are too late in beginning to thin them, and continue the work beyond the period when it should have stopped. It will be found on carefully examining the growing trees in the forest that from one or other of these two causes the value of the mature crop is much less, sometimes immensely so, than it otherwise would or should have been. The delay in commencing to thin is accounted for on various grounds, but the most common are first in order to be able to derive profit from the thinnings. This profit, though much talked of, and bulking largely in the minds of many proprietors, is little more than a vision or mirage in the desert. Having made several fair and impartial experiments of thinning in different parts of the country, and when and where the thinnings realised as high prices as they are ever likely to do again there or anywhere else, and we never in any case received as much for the first thinnings

as paid the work. We have generally put the cost of thinning a Fine or Fir plantation done at so early an age that no profit was looked for, or expected, at 5s. to 6s. per acre, and this, as must appear self explanatory, is simply adding that sum to the cost of forming the plantation. If not actually doing so, it practically is so, for it must be years yet before any profitable return ought to be obtained from the plantation. What is earnestly desired to be made plain is, that while there is an apparent loss incurred by thinning Pine and Fir plantations before they are capable of yielding profitable returns, there is yet actually less loss by this than by the other and more common practice of delaying thinning till a certain amount of revenue is derived for the thinnings. Another adverse circumstance presents itself in the difficulty of handling the thinning axe. The trees had been planted at about 4½ feet apart, and if grown to fifteen years old, or even ten years in some cases, the tallest will be 15 to 20 feet high, and the side branches of the adjoining trees twisted and interlaced with each other; if quite dead they are easily broken off, at least in the case of Scots Pine, but if only partially dead, and the crop is Larch or Spruce, they are tough and wiry, and consequently entail much toil and labour in performing the work. The laborious, disagreeable, and expensive work of this first thinning is not yet over, for the thinnings, whether pruned out or taken out of the plantation with the branches on, require to be carried through a dense thicket of spray. The crop as now thinned stands at about 600 trees per acre of Scots Fir or Spruce, and about 1,200 if Larch; but the trees have not yet shed their branches, nor are they to be pruned off by artificial means, not yet having fulfilled the end and purpose Nature designed by them.

The ideal commercial tree is a branchless trunk of cylindrical form—tall, clean, straight, and free form knots and blemishes. A branchless trunk, however, though a subject to be longed for, especially as a commercial product, is neither easy to secure nor to be regarded other than a prodigy equally rare and costly. It will be seen by any one who takes notice of it, that in a forest composed of trees of different sizes, but of nearly the same age, such as are common in the Pine forests and woods of Strathspey, Deeside, Morayshire, Inverness-shire, Rossshire and other parts of the country both north and south, that clean grown trees with fewest branches are soonest ripe and mature, but fall an early prey to disease. It is no rare thing to find a fine clean tree clear of branches too near the top, of 100 year's growth, containing only 10, cubic feet of timber or even less, ripe and ready to cut growing at the rate of a quarter of a cubic foot annually, and depositing layers of wood scarcely one-sixteenth of an inch thick, literally adding a quarter of a foot to the surface, and losing as much or more from natural internal decay, and worth only 5s. Beside this tree grows another, well branched, containing over 50 cubic feet, and still making wood; growing at the rate of 1½ cubic foot yearly, and depositing annual layers about one-eighth inch thick, and worth at least 25s. each.—*Gardeners' Chronicle.*

VALUE OF TEA, COFFEE AND COCOA AS FOOD.

Some very interesting particulars of the relative merits of the above-named articles as food is given in a recent hand-book published under the auspices of the International Health Exhibition by Alexander Wynter Blyth, M. R.C.S.,&c. After calling attention to the numerous varieties of tea, the writer refers to the complexity of substances that are to be extracted, and enumerates no less than sixteen components, viz., essential oil, theine, botric acid, quercetine, tannin, quercitrinic acid, gallic acid, oxalic acid, gum, chlorophyl, resin, wax, albumen, woody and coloring matters and ash.

It must be remembered, however, that many of the above, such as wax, coloring matters, albumen, woody fibre, gum, and resin are common constituents of plants and are in no way distinctive of the tea plant. The alkaloid theine, otherwise called caffeine, can be obtained in beautiful silky crystals of the whiteness of snow. There is not much difficulty to demonstrate the presence of theine in tea, and the following method is given:—Place one or two tea leaves in a teaspoon and add a little water; boil almost to dryness over a spirit lamp; then add a pinch of dry magnesia and make the tea leaf and infusion a sort of paste; on carefully heating and holding a slip of glass over the spoon, theine will sublime or condense in crystals upon the glass.

The quantity of theine in tea varies from 1 to 3 per cent, and in a cup holding a half pint of tea there would be on an average thirty-eight grains of solid matter, which would include seven and a half grains of tannin, two and a half grains of theine, and a fraction of a grain of essential oil. The writer, in a table showing the component parts of a pound of tea costing at retail about 60 cents, shows that in purchasing a pound of tea a person only purchases nine ounces of active substances, which may be considered from an economical point of view rather a dear article of food. In two cents' worth of fifty-cent tea a person only buys 162 grains of the components of the tea.

In speaking about coffee, Mr. Blyth calls attention to the changes in the berry produced by the action of roasting, causing the volatilization of a small portion of the caffeine (theine), a partial change of the sugar into caramel, a general breaking up of the oil and albumen cells, with the extraction of gas and water, and the development of a very powerful and volatile aromatic substance. The table giving the component parts of a pound of coffee shows that a person purchasing a pound of the berry buys only 8¾ ounces of useful matter, a little less than in a pound of tea. Calculating coffee to cost from 20 to 36 cents at retail, Mr. Blyth contends that it is comparatively dearer than tea, for the simple reason that so much more of the ground berries have to be used.

In speaking of chicory, Mr. Blyth considers it a very harmless root with no particular physiological action. It is added to coffee by some in order to make a weak infusion of coffee appear strong.

In reference to cocoa, the writers calls attention to the variety of cocoa and chocolate preparations before the public, and submits a table giving an average composition of the majority of popular brands. Mr. Blyth calls attention to two particular constituents of cocoa, viz., theobromine and cocoa butter. Theobromine is an alkaloid somewhat analogous to theine in tea and caffeine in coffee. Cocoa butter is a yellow concrete oil of the consistency of tallow. It has a brown color and agreeable taste. It never becomes rancid however long it may be kept.

If we consider the large amount of starchy matter, fat, albumen, &c., cocoa and chocolate are beyond question the cheapest, as they may be considered as much food as drink. In one pound of cocoa there are no less than 14 ounces of useful matter, and at an average of 30 cents the buyer buys for 2 cents 398 grains, or nearly an ounce, more or less nutritious substances.

Considering that cocoa contains nearly twice as much nutrition as tea and coffee, it is strange that cocoa and chocolate have not become more popular, particularly with the working class. Still there may be something in the fact that it only contains 1·24 per cent of theobromine, the stimulating principle, while tea will average nearly 3 and coffee 2½ per cent. of theine. It is not so much as food that people drink tea and coffee, but as a stimulant, and, no doubt, in countries where the people work the hardest and suffer from nervous exhaustion, there is where tea and coffee are the most popular drinks.—*American Grocer.*

TEA MITE AND TEA BUG.

[The following uncomplimentary notice of Mr. Wood-Mason's book appears in the *Indian Planters' Gazette.* We may say, that, having received a copy of the book, we find, that, while the tea mite is figured after an enormous fashion, there is no representation of *Helopeltis.* This is disappointing.—ED.]

It will no doubt be in the remembrance of many of our readers how Mr. Wood-Mason was deputed to the tea districts, at the suggestion of the Calcutta agency houses and how, after studying the subject for some months, he flashed a telegram to the Chief Commissioner of Assam who in turn remitted it to the Deputy Commissioner wit

instructions to transmit it to all planters on their different commissionerships. Amidst the splendour of this telegram, Mr. Wood-Mason took his departure, leaving the planting community as much at a loss with regard to a remedy, as they were before, but stupified into silence, by the very boldness of opinion, advanced by him as original, but which old planters had known for years. In case our readers may have forgotten the purport of his telegram, we may state that it told how the eggs of the Tea Bug were deposited in the tea shoot, and recommended plucking off every soft shoot on a bush, so as to destroy the eggs of the bug. Such a course may have seemed feasible to a man who had not studied how the tea leaf is produced, and how carefully a planter looks after his plucking to prevent weakening his bushes by *over plucking*, not to speak of stripping it of every soft shoot. No botanist would have proposed such a course, though a botanist might have advocated the total destruction of tea bushes and adajacent jungle whenever the pest appeared, and suggested that Government might bear part of the loss. This cure of Mr. Wood-Mason's would be worse than the disease; for if it were persisted in there could be but one end to the bush, and that would be its utter annihilation. The way in which the tea bug laid its eggs in the young succulent shoots was, or had been, known to very many old planters, and if we mistake not Messrs. Stuart Brothers of Koomber and Larsingah, who had, from bitter experience of its ravages, given a good deal of attention to the subject of the bug, could have enlightened Mr. Wood Mason on many points which he claims as original. We know of more than one planter, who, from information received from the Messrs. Stuart Brothers, not only could successfully point out where the eggs lay in the shoots, but had hatched young bugs in bottles from the eggs. Mr. Wood-Mason, too, we understand, gave it as his opinion that the insect did not exist or attack any kind of jungle, but simply preyed upon the tea. This, we are convinced, could be easily controverted by what many of our old planters have seen. Mr. Wood-Mason was sent up to the tea districts, as we stated above, by Government, at the instigation of the Calcutta agency houses, and with a view to find out a remedy for what is more commonly known in the tea districts as the *blight*. In this he has signally failed. He has written two very interesting monograms. Planters value monograms very highly, but they would value a practical method of getting rid of these pests more highly still. If any planter should turn to Mr. Wood-Mason's book in the hope of finding any thing that will be of the slightest value to him in his work he will be disappointed. If any planter goes to the little book in the hope that at last he may have dropped upon something that may help him to cure the "blight" which has cost him many a sleepless night, cost his shareholders maunds upon maunds of tea, and made the difference between a handsome profit and a small loss, he will light on some such sentence as this—"The respiratory processes of the egg shell so closely resemble the fine pubescence which clothes the surface of the shoots, as to be quite undistinguishable from it to the unaided eye; and to eyes unaccustomed to Zoological work, even with the aid of an ordinary lens, so that it is no wonder the planters had altogether failed to find the eggs of the pest after these had left the bodies of the females."

Many planters were quite well aware of the habits of the insect in laying its eggs, and we have named two, and others could be named if necessary. The way in which the insect lays its eggs does not seem to give any indication how to get rid of it. The eggs are laid in the soft succulent shoots of the bush and to leave portions of which on the bush is absolutely necessary to its existence, so that some other method must be found out to destroy the insects than the suicidal one recommended by Mr. Wood-Mason. There is no doubt that a very large fortune awaits any scientific man who will devote his time not only to the study of the habits of tea pests, but to a practical method of preventing their ravages. We are fully aware that a knowledge of the habits of the insects is necessary to draw any inference or offer any suggestion as to a cure, but when the subject is taken up by a scientific man one expects to learn something which he did not known before, and disappointment is felt when on practical result is forthcoming.—*Planters' Gazette.*

ORCHIDS.

[A paper read by Mr. D. Birt before the Caterham Horticultural Society, December 12th.]

It would perhaps be not unfitting to begin the discussion of our subject by giving an answer to the question, "What is an Orchid?" by showing, that is to say, in what respects Orchids differ from other plants. Their chief peculiarity consists by no means in the beauty of their flowers—for many of these flowers would scarcely be thought beautiful—but that which marks off the Orchids from general plant life is the curious structure and wonderful contrivance which their flowers exhibit and which they possess for the accomplishment of a special purpose, which I will explain presently. It is one of these special points of flower structure which has given rise to the term "Orchid," but as I think we can best turn our attention to the flowers of these interesting plants after we have considered one or two other aspects of our subject.

A common idea about these plants is that they all grow in very hot countries, and that they all need very hot quarters when brought under cultivation. The fact is, that though the forests of the torrid regions, and particularly the South American forests, are very rich in Orchids, yet some of those which bear the finest and most interesting flowers are found in climates almost temperate. Orchids, indeed, are found in nearly all parts of the world except the very coldest and most arid, and of the 3,000 species which have been described, thirty-eight are found amongst the wild flowers of Great Britain.

Orchids have two very distinct modes of growth. A large number (the tropical kinds, more especially) grow on the boughs of trees. They appear in no way to injure their big friends who thus hold them aloft, shade them from the fierce sun, and "rock them in their arms so wild." Hence Orchids are not classed with parasitic plants (such, for instance, as Mistletoe), which feed on the juices of the trees they occupy, but are termed epiphytes, which means a plant growing upon a plant. These epiphytes, or tree Orchids, form one of the two divisions of the Orchid family.

The other division consists of the terrestrial Orchids, as those are called which grow down upon the ground.

I will take two or three examples of these groups, first calling attention to the Cattleya. This is one of a large section comprising many sorts differing less in the character of their growth and the shape of their flowers than in the colouring of the latter, which is very various in the different species. Though the mode in which it is grown—viz., on the top of a clay pot, with a little peat under it, is found to be the best artificial mode of cultivation, it doubtless grew with far greater vigour high up on its native tree in some Brazilian forest whence it was brought. You must imagine it so growing; in hot sunshine by day modified by the overhanging leafage, at night blown by the cool night winds from the Atlantic, and anon during its growing season drenched by the downpour of a tropical thunderstorm. The base of each leaf (that upon which it grows) is much more than a mere leafatalk. It is, in fact, a reservoir of moisture upon which the leaf subsists during the long season of drought to which the plant is exposed. But for this reserve of moisture the plant would die in the hot rainless part of the year, which continues for some months. Due allowance has to be made for this when the plant comes under cultivation, and hence when Cattleyas go to rest after completing their growth for the year we give them scarcely any water. Under this treatment these pseudo-bulbs or reservoirs frequently show signs of shrivelling by partial loss of their contents, but when the growing season comes round again, and water is again given in more abundance, the bulbs get plump again.

We will next take the Odontoglossum, also found on the American Continent, and representative of the class of earth Orchids which are found in great variety in Central America. The particular species I have selected is named O. Alexandræ, because it was introduced to England about the time that our future Queen Consort first came to our shores as the Prince of Wales's bride. This Orchid, though it is a native of Bogota, and, there-

fore, as near the equator as many of the Cattleyas, is found only at high altitudes, and experiences consequently a much cooler climate than the Brazilian Cattleyas. Travellers describe it as growing in an almost perpetual mist, the result of which is that it endures very subdued sunlight, a large amount of air moisture, and, as might be expected, is found surrounded with mosses and lichens and other moisture-loving growths.

The third example is a Dendrobium, of which there is a multitude of varieties. It is an epiphyte. You must imagine this variety, which comes from India, growing in some dense jungle amidst luxuriant vegetation, its long growths not turning upwards, as these are trained, but hanging down possibly over a stream of water from some overarching branch. These plump growths are called pseudo-bulbs, and serve the same purpose as the corresponding portion of a Cattleya—that is, as a reserve of moisture for the plant's sustenance during the long rainless season. As in the case of the Cattleya, each leaf has its own reservoir. Each pseudo-bulb of the Dendrobium carries many leaves ranged symmetrically down it. From these bulbs, after the leaves have fallen, charming clusters of flowers emerge. The terrible and the beautiful in nature are often very close to one another, and it may well happen to the traveller, as he turns away from the scene of floral beauty, to encounter the gaze of a tiger watching him with not less interest than that with which he has been gazing on the Dendrobiums. Well for his chances of escape if the tiger has not yet completed the digestion of his last victim.

Our fourth plant is a Cypripedium or Lady's Slipper, so called from the slipper-shaped pouch at the base of the flower. This section is the most widely distributed of any Orchids. Varieties of it are found in every quarter of the world, and in England we possess one native variety, Cypripedium Calceolus, which is said to be found more especially in the north of England. The Cypripediums have no pseudo-bulbs, because they are not called on to bear drought. They are found in moist places at the foot of trees, or protected by moist rocks and stones. The plant I am specially referring to comes from Sylhet, and is called C. insigne. It may be of interest to contrast the flowers of the ordinary type with those of this superior variety called C. insigne Maulei, after the firm Messrs. Maule, of Bristol, who were fortunate in importing some plants of it many years ago. The upper portion of the flower has a much larger colouring of white than the normal type, and there are besides some handsome purple spots on the same part of the flower which are wanting in the common type.—*Journal of Horticulture.*

BRITISH GUIANA:

REPORT TO THE GOVERNMENT ON THE PROGRESS AND CONDITION OF THE BOTANIC GARDENS OF DEMERARA.

Introductory.—As the Loan of $240,000 raised for the purchase of the land and laying out and planting of the Botanic Gardens is now, after five years' labour, exhausted, a brief introductory review of what has been accomplished is desirable. If the present state of the gardens be compared with the plan originally approved by the Court of Policy, it will be seen that the whole work there sketched has been carried out, except, only, in providing a glass house, the erection of which has been postponed to the present year in favour of pushing forward with the (for the time) more urgent wants of the institution, and some slight modification found desirable in the course of the serpentine drives which run through the ground beyond the flower garden. My past annual reports have given in detail the progress of the work, so that I need only summarise here its principal features. It comprised making up the land for the flower garden with the soil supplied in excavating the lakes, subsoil draining, laying out and planting it, supplying a system of irrigation, and making the serpentine drives, which extend upwards through the grounds beyond the flower garden. It is true that these roads have not yet been opened to public traffic, but they only await the approaches to be made up to the iron bridges that connect them with the orinoque avenue drive at their farther end. These bridges have been put up by the Public Works Department. Ample draining trenches have been made that enclose the whole block of land. A steam engine and lofty tank provide water for irrigation; propagating houses have been built in the nursery, and residences for the officials in charge of the institution. All this was designed on the plan, but in addition thereto a drive, the chief resort in the gardens, has been made under the old orinoque-tree avenue that was found on the ground, and extending beyond it to the Lamaha canal boundary on the east. Two large lakes, not originally contemplated as necessary, have been dug, and their contents used in making up the surface, or for burnt-earth. A broad drive quite round the outside of the gardens and grounds, about two and a half miles long, has been in a large measure formed, though only a small part has, as yet (for reasons explained in my last year's report) been actually completed. The shelter-belt on the land to the windward of the gardens, purchased for the purpose from the proprietors of *Bel Air* estate, is also an important and thriving addition not contemplated at first; and on the south side of the ground, outside also of the block, fourteen acres, part of the original Vlissengen estate, though not recognised as belonging to it when it was taken over, have been acquired and opened as an experimental ground. Lastly, an avenue of trees to shade the outside south drive has been planted, and a single line on the north drive, with much minor work.

Avenues.—On collecting and comparing specimens of the bird-vine which is such a nuisance on the orinoque trees of the avenue, I have found that it is composed of three species—*Loranthus syringæfolius*, *L. Theobromæ* and *L. ruficaulis*. The former is the prevailing species, the other two being comparatively rare. Indeed the orinoque tree does not appear to be a host-plant for *L. ruficaulis* at all, as I have only found it on two or three of the other kinds of trees in the avenue. It infests a large *Spondias* alone, neither of the other two ever being found on this tree, though *L. syringæfolia* is a dissolute species that establishes itself with freedom on a great variety of trees and shrubs everywhere in the gardens. Like many other parasitical and epiphytal plants, some Loranthaceæ are restricted in the subjects upon which they grow, and this fortunately greatly limits their prevalence, while others adapt themselves to a more or less greater variety of host-plants. These, on cultivated trees, are a great nuisance. The seeds of *L. syringæfolius* germinate on any surface, though, of course, if it be an unsuitable one they soon die. A few months ago I picked up a bird in the grass under the avenue, and found it clogged with the viscid, germinated, seed of this species. Even in their earliest state of active life the influence is very pernicious to the vegetation subject to it.

Nursery.—Some improvement has been effected in the nursery by raising the surface of the beds through two of the blocks, and filling in the cross-paths which were found unnecessary and which, being twelve feet wide, occupied a good deal of space. The land here is the lowest in the gardens, and had to be raised two feet in some places. Much of the ground is now devoted to raising large stocks of economic plants for sale, such as coffee, cocoa, oranges, sugarcane, &c. In addition, it has been planted through at proper distances apart with mangoe, orange, litchi, and coffee stock plants. The mangoes I am able to multiply by inarching, but I find great difficulty in meeting the demand for other fruits, as there are no trees yet advanced enough in the gardens to produce seed, from which stocks could be raised. In all these I have to trust to obtaining supplies from the islands and other sources, about the success of which at the time plants are desired there is, of course, frequently uncertainty. I have before mentioned that the large border in the nursery enclosure has been kept chiefly for economic plants, of which already it contains a considerable variety. Some excellent soil was obtained for this border by deepening the racecourse trench next the gardens, which was allowed by the racecourse committee.

I am sorry to say that the variety of scale and other insect pests that affect the nursery stock increases from year to year. As in the case of the parasitic birdlime, spoken of on a previous page of this report, several of

of a poor plant which grows on the English coast. The them attack only one species. Not much, however, is gained from this limitation of their ravages, for hardly anything is free from attack by one species or another. This is particularly the case with the large stock of young palms. *Mauritia flexuosa* and *Areca catechu* I find it very difficult to raise at all. To keep the scale down by hand washing is an endless task. I have tried the emulsion recommended for the orange scale, made of oil, milk and soap, but it has to be used with great care. If strong it kills the plant when washed from the leaves into the heart, and if weak it does not kill the scale. All palms, too, will not bear it of the same strength. I find the best plan is to dip the foliage of the plant in, and then lay the pot down on its side to prevent the solution draining into the heart, washing it off with soft tepid water the next day. Caterpillars are very destructive, too, to palms if not watched for closely, but chiefly to the larger plants in tubs and to those planted out. A kind that is bred on the almond shade trees in the nursery, and which travels to other plants near, is one of the worst. In the propagating house caterpillars, and these the smaller kinds, only affect ferns. Scale and different kinds of mealy bug attack several kinds of orchids too. An excellent report by Dr. McLachlan on specimens of the local orange and lime tree scale which I sent home for examination, was received by the Government from the Colonial Office, and published in the *Official Gazette* some months ago. The scale of this colony appears to be a distinct insect from that which is so destructive to orange trees in the Southern United States, and Dr. Victor Signoret, to whom Dr. McLachlan submitted my specimens for his examination, has named in *Diaspis aurantii*, it being before an undescribed species. It attacks alike oranges, limes, and the Indian bhal—*Egle marmelos*—but, here at least, seems to damage most the former. [Who first described *Helopeltis antonii*?—En.]

Economic Plants.—The following economic plants among others of less importance have been propagated in the nursery in more or less quantity:—

Coca.—Seed of this is now produced plentifully by the plants in the gardens. It has to be watched carefully as it ripens, for birds are great devourers of it. The fruiting season is during the summer months. On a visit to the Pomeroon River I obtained seed of another species of *Erythroxylon*, which I found about Indian settlements, and as plentifully laden with seed as the coca is here in its season

Cocoa.—A good supply for propagation of very excellent cocoa seed was obtained by the good services of the Commissary of the district, Mr. Harcourt, from the Berbice River. It consisted principally of two varieties, with a few pods each of two or three other forms. The collection appeared to include the best forms grown on the islands. Taking them in the order of their quantity, I made the following notes on them. 1.—A large pale-yellow, deeply ribbed and rather corrugated pod, sharp-pointed and ovate-lanceolate. 2.—A large yellow pod, turning brown, smooth, with very shallow ribs, ovate-oblong, acute-pointed. 3.—A shorter pod than number 2, which it otherwise much resembles, but the ribs are rather less distinct. 4.—Is perhaps the same as number 3, but the pods have a distinct appearance, and are dark brown. 5.—Perhaps a form of number 1, but the pod is a bright reddish colour. Numbers 1 and 3 seem to be the best kinds; their pericarps are thin, and they have rather more seed than the others. Mr. Harcourt sent me several lots, and in each case the kinds bore the same relative proportion to each other. Old cocoa trees are found, grown almost into forest, both on the Berbice and Canje Rivers. They are of course the remnants of old plantations. Their healthy and robust growth indicates how well the cocoa industry would thrive on the banks of the rivers of this colony, and it is interesting to know that a few plantations are being established.

Kola-nut.—The west African kola-nut, which is very extensively used by the natives as a masticatory, it having the quality of stimulating the flavour of, and, as well allaying the natural craving for food, and about the properties of which a great deal has of late been written, has been obtained by seed from Jamaica. A plant was also received from Kew. In Jamaica it is a naturalised tree, known by the name of Bissi or Bischi, and was probably first brought to the island by slaves. Of the plants raised from the Jamaica seed I have distributed publicly a few; the rest I have planted as stock plants for the gardens.

Ceará-rubber.—I am indebted to the Manager of *Smythfield*, Berbice, Mr. W. H. Quincey, for two plants of the ceará-rubber tree; and a packet of seed has since been received from Dr. Trimen, the Director of the Ceylon Botanic Gardens. The larger of the plants received from Mr. Quincey is now over eight feet high, and growing rapidly. As I pointed out in describing the tree in my first Indiarubber Report, an immense area in this colony is well suited for its cultivation.

A new Cabbage-palm.—It is generally supposed that the cabbage palms in Georgetown are all of one species—but I find they consist of three, though of two of these the specimens are few. When first I came to the colony, a plant that was growing at the Alms House on the Brickdam, struck me as apparently distinct from the common species; but it was subsequently cut down, and the matter passed from my mind, till one day a few months ago, when riding down New Market Street for the first time, I noticed in an ally belonging to the corporation, two or three large trees of the same, in full flower and fruit. Mr. Hill, the Town Superintendent, very kindly allowed me to gather full sets of specimens for examination, the flower and fruit of which showed it to be a perfectly distinct type. The third, which is well distinguished by habit, I have not been able to procure flowering specimens of as yet; all the trees I have found being too high for their heads to be reached, even with the aid of a long ladder. Of the second species I have raised a good stock from seed, and a very fine young tree, fifteen feet high over all, and two feet six inches in circumference of stem, has been successfully transferred to the gardens from a yard on the Brickdam, where it was found growing. These three cabbage palms are all species of *Oreodoxa* or *Euterpe*. The common cabbage palm of the islands I have repeatedly tried to introduce by importing seed, which, however, in each instance, failed to germinate. Success however has attended the importation of plants. I am indebted for these to Mr. F. Gurney, of St. Felix, Grenada, who was good enough to send several in a case of plants native of that island.—G. S. Jenman, Government Botanist and Superintendent Botanic Gardens, 19th June 1884.

PLANT IMPROVEMENT BY HYBRIDISATION.

A subject of much more than ordinary importance was brought before the Royal Society at its last monthly meeting by Mr. Pink, of the Botanic Gardens, who read a paper on the hybridisation of plants. In new countries this matter has a special interest; it is, of course, easy enough to introduce the fruits and other products of older countries, and many of them thrive and give good returns to the cultivator, but too often they do well only for a time, and then begin to deteriorate, sometimes very rapidly. An instance of what may be done by careful selection of plants, good cultivation, and hybridisation was mentioned by Mr. Pink in his paper. The first apple-trees planted in America by the early colonists retrograded until the fruit were no better than "crabs." Now their apples are equal to any in the world. He might have gone further had he been treating the subject more fully, but he was dealing with improvement in the product apart from the question of resistance of disease. Pursuing it another step or two an additional advance can be shown; for, whereas the apple-tree is in an extraordinary degree the victim to what is commonly known as American blight, varieties have been produced which are so free from its attacks that, when surrounded by other trees whose stems and branches are completely covered with it, they are quite clean. Many similar examples might be adduced, but it is unnecessary to go further, and we come back to the point from which we started—that hybridisation, combined, of course, with careful selection and good cultivation, is the key which will unlock the door and bring to light the secret by which diseases in plants of all kinds may be modified, if not overcome, the produce improved, and the cultivation of grain crops, fruits, flowers, and vegetables made remunerative. Our finest cabbages and cauliflowers are the descendants

same type is found beside the shores of New Zealand, and is said to be the degenerate offspring of seeds which were distributed among the natives by Captain Cook. This, however, is uncertain. That the cauliflower of the present day should have been produced from the *Brassica oleracea*, "with wavy sea-green leaves, tending to no head, and flowering like wild mustard or charlock," ought to be sufficient encouragement to experimentalists. So much has already been achieved that it would seem vain to fix a limit to further improvements.—*Queenslander.*

ESSENTIAL OILS.

Among the various devices for making the soil of England commercially profitable, the growing of flowers for the sake of the essential oils, though it can hardly become a great enterprise, deserves encouragement wherever success is possible. A considerable acreage of land at Grove, near Canterbury, has lately been planted with lavender and mint, and the result has proved so successful that it has been determined to establish extensive works on the spot, in order to carry on the process of extracting the essential oils. So far there is no reason to question the profitable outcome of the venture, though, of course, the demand for the oils of lavender and peppermint is more limited than for wheat or Kentish pippins. Still, they are used in more industries than people generally know of, and there is, moreover, this to be said for them, that if the market is not so great, neither is the competition for purchasers so keen. No discovery of the laboratory has ever yet managed to supply an ether which will replace the natural scents elaborated by Nature in the cells of wild herbs. Nor can the cultivator of the plant yielding the precious oils contrive to so stimulate his crops that the products of one locality will fetch the same figure as those of a more favoured region. It is not more hopeless for the tobacco grower of Germany to pass the rank leaves which have matured under the Teutonic suns for real Habana, than it is for the flower farmer of one spot seemingly as suitable as any other to deceive the perfumer with the tale that the herbs have been nurtured in a soil, the reputation of which stands in greater esteem. Curiously enough, it does not always follow that the lands of sunshine are always the best for this description of harvest. Thus, the shores of the Mediterranean, near Grasse and Nice, are the best localities for the orange and mignonette, the perfection of the essential oils extracted from the flowers and leaves of these plants requiring low, warm, and sheltered spots. But the violet grows sweeter and sweeter as we ascend from the lowlands, and is most highly scented just as the foot hills of the Alps are approached. Again, though France and other Southern countries send us plenty of oil of peppermint and lavender, none of it can rival that grown at Mitcham, in Surrey, almost a suburb of London, which is said to bring eight times the price of the foreign oils. It is thus clear that the Kentish flower farmers have some margin within which to work. Every year there is imported into this country between two hundred and three hundred thousand pounds weight of essential oils, the greater portion of which—leaving out of account cassia, vanilla, cloves, and lemon, which are scents of far-way lands—could just as easily, and a great deal more profitably, be produced within the bounds of the United Kingdom. Lavender, for example, has for centuries been grown at Hitchin, in Hertfordshire, and as a commercial speculation it dates back for at least sixty years. The plants at present in cultivation do not produce seed, being propagated by slips or by dividing the roots. The crop is, however, somewhat precarious. During the severe winter of 1860 many of the plants were killed, and of late years a peculiar fungus has so decimated them that the price of the oil has, in consequence, risen considerably. At Market Deeping, in Lincolnshire, where lavender was formerly grown, the business has been discontinued on that account. Hitchin, however, still harvests the crop of about fifty acres—a sandy loam with a calcareous substratum being regarded as the best soil for the purpose, while the most favourable position for the lavender plots is a sunny slope which the fogs do not reach, and where light airs blow freely, but which is not so high as to be in peril of early frosts. At Mitcham, Carshalton, and Beddington, localities all near each other, about three hundred acres are still under lavender, and a considerable area under mint, though here as elsewhere, for the reason mentioned, and other causes connected with the altered habits of the people, the culture is reported to be on the wane. At one time it was an important industry, and the Church tithes of the parishes in question were proportionally valuable. The lavender flowers are collected in August and taken direct to the still, when the turn out of oil to a great extent depends on circumstances beyond the control of the farmer. If June and July have been bright the result is satisfactory; but if there has been dull, wet weather during these months, only half as much oil will be expressed. The oil from the stems is ranker and less valuable than that from the flowers; consequently, the portion which first distils over is collected separately, that which appears after about an hour and a half bringing a lower price. Should the flowers be distilled separately a finer oil is obtained. But as the extra labour demanded by the operation adds about ten shillings per lb. to the cost of the oil, it is not usually done, since the "fractional distillation" described effects nearly the same end. After three years the oil—which has been mellowing up to that date—deteriorates, unless it is mixed with alcohol, or redistilled. In France, Piedmont, and especially the vicinity of the villages of the Mont Vextoux district, and those to the west of Montpellier, the collection and distillation of lavender is widely practised; but the very best French oil does not approach in price that of the English article, and the cheapest varieties are made by distilling the entire plant. Some oil comes also from America. Near New York the plant is affirmed by Professor Johnston not to be very hardy, but in the neighbourhood of Philadelphia it is grown in considerable quantities, chiefly for "sachets," or sweet scent bags, and for "laying up linen," a use for lavender which is, unhappily, not on the increase in this country. The *Lavandula spica*, which yields the "oil of spike," is a variety which cannot be grown in this country except in very sheltered situations, and is in any case inferior to that yielded by the common species. Peppermint culture requires no such nicety, and the distillation of the leaves is a very simple operation. The oil is still in good demand as a flavouring for lozenges, and as one of the drugs used in the Pharmacopœia both as a stomachic and as a means of disguising the taste of other medicines. The cultivation of roses for the distillation of the precious attar would, in our uncertain climate, be a losing speculation, taking one season with another, though the profits for a fine crop are tempting enough to send some discouraged wheat-growers into the business. The oil yielded by roses is very little; hence it is said that twenty thousand blossoms are required to yield a rupee weight of the "attar," which sells for £10 sterling, a little fact which may suggest to the lady that the "real Oriental attar" which she bought in the Stamboul Bazaar for 10s. the ounce was not quite what the Moslem merchant so loudly swore by the Prophet it was. In reality, the true attar is almost invariably adulterated with sandal-wood oil, or diluted with sweet salad oil, even in the Indian bazaars close to the far-famed rose gardens of Ghazepore. This seems almost pardonable when we remember that, during unfavourable seasons, it will take as many as 1,000 roses to yield two grains of the oil. In the forenoon the red blooms are collected by hand and distilled into clay stills with twice their weight of water,—the water which comes over being set to cool all night and throwing up the thin film of oil which covers it in the morning like cream on new milk. This is the attar, which must be carefully swept off with a feather, and transferred to a small phial. After repeating this operation night after night, and morning after morning, nearly the whole of the oil has been extracted, the little which it is impossible to separate so flavouring the liquid that it is sold as "rose water," just as the minute particles left in the course of distilling lavender of peppermint are known as the "waters" of their essences. It is also quite out of our power in England to compete with the South for the production of jasmine oil, which is almost as costly as attar of roses, the "neroli" which is obtained from orange flowers, or the *petit grain* extracted from its leaves. But there is no reason why the anise, the carraway, and the iris should not be more grown for the purposes indicated, nor why the rosemary and the juniper should not be pressed into the service of the perfumer by the hands of the English agriculturist. At

present attar of roses reaches this country mainly from Smyrna and Constantinople, the oil of lemons from Sicily and Portugal, bergamot from Sicily, anise from Germany and the East Indies, and oil of cloves to a small extent from the Malay Islands, though it is believed that a large amount is distilled by the London wholesale druggists. Carraway is, however, still mainly a home product, and should the experiment pronounced so successful in East Kent be extensively followed, the not inconsiderable quantity of oil of lavender and oil of peppermint distilled in England is likely to be largely increased.—*Standard.* [The article is incomplete as failing to notice the considerable quantities of lemon grass and cinnamon oils which reach Europe from the East, the first mainly, and second almost extremely, from Ceylon.—Ed.]

A Coffee Plantation has been established by a landowner in the neighbourhood of Rome. It is stated that he realised a fair profit with this year's harvest, which consisted of 2 tons of coffee per hectare.—*Nature.*

Successor to the Late Dr. Voelcker.—At a meeting of the Council of the Royal Agricultural Society of England on Feb. 6, Dr. John Augustus Voelcker was appointed Consulting Chemist and Director of the Society's Laboratory, in succession to his father, the late Dr. Augustus Voelcker.—*Gardeners' Chronicle.*

The Tree Tomato (Cyphomandra betacea).—The plant (belonging to the natural order Solanaceæ) is of shrubby habit, and 5 or 6 feet high. It is not generally known, and seldom used, in Jamaica, but it is without a doubt a fruit that should be more largely cultivated, as it answers in every respect the purposes for which the ordinay Tomato is esteemed. Plants are easly raised from seed, which come into bearing in about two years. They are very prolific bearers, and the fruit is available during the winter months—November to March—when ordinary Tomatos are not so easily obtained.—D. Morris. [A plant bearing fruit may now be seen in the Temperate-house at Kew.—Ed.]—*Ibid.*

Mohwa Sugar.—A note on Mohwa sugar from Bassia latifolia was recently communicated to the Agricultural and Horticultural Society of India. In this communication the writer refers to the presence of sugar in the petals of the flowers, and says that this "indicates that the rising sap of the tree in spring, and just before the flower-buds swell, must be rich in saccharine matter, and if so tapping the Mohwa trees in the same manner that the Sugar Maple (Acer saccharinum) of North America is tapped may lead to the production of sweet sap, which on being boiled and concentrated would yield sugar." It is suggested that it would be well worth while tapping or bleeding the species of Bassia for their sap, and if this should be found to contain true sugar, the discovery would be one of considerable importance, for a large and very profitable trade would be called into existence in India.—*Ibid.*

Snow Mountains of Eastern Africa.—At the last meeting of the Royal Geographical Society, Mr. H. H. Johnston read a paper on an expedition to Mount Kilimanjaro and the Snow Mountains of Eastern Africa. Mr. Johnston said that he went to the alpine district of Eastern Africa as head of an expedition planned by the British Association and the Royal Society. Leaving Mombas towards the end of May last at the head of 120 men, of whom about a quarter deserted on the road, he reached Kilimanjaro at the beginning of June. The cultivated zone, he found, ended at a height of 5,500 feet At 10,000 feet the thermometer descended every night 1° or 2° below zero. While mentioning this fact he gave details showing that the land even up to that elevation is both beautiful and fertile. He reached a height of 16,315 feet on Mount Kilimanjaro—something like 2,500 feet from the summit—where the fog prevented him from seeing anything but stones and snow. Notwithstanding the latter, his thermometer recorded a temperature 3° above freezing point. The leeturer went on to describe his attempt to ascend Kibô, the monarch of the range. Here he learned that the buffalo, the koodoo, and the elephant wander as high as 13,000 or 14,000 feet. He reached the snow region of Kibô, but not the summit, being compelled by bad weather and unwilling followers to return. The Rev. Archdeacon Farler, as one familiar with the country visited by Mr. Johnston, pointed out that the lower slopes of the Kilimanjaro Mountains were very suitable for European settlers.—*Ibid.*

How Soil Is Made Fertile.—The current number of the *Journal of the Chemical Society* contains a valuable communication from Mr. R. Warington on the subject of nitrification, being the result of five years' patient investigation in the laboratory of Sir J. B. Lawes at Rothamsted. The practical conclusions from these important results are obvious. The experiments clearly point out why liquid manures should always be applied to plants in a state of great dilution. The effect of liming soils will also be better understood. Further, when rich stable or farmyard manure is left exposed on the surface of the land, there is undoubtedly in dry weather a considerable loss of ammonia or plant-food, as the fermented urine in the dung is in a condition too concentrated either for nitrification or the retention of ammonia by the soil. A similar loss of plant-food would occur in very dry weather when sheep or cattle are fed on the land.—*Ibid.*

New Cultures in South Australia.—A recent number of the *Colonies and India* states that an interesting report from the Conservator of Forests in South Australia has been laid before Parliament on the question of the cultivation of Olives, Dates, and white Mulberries for sericulture. The different kinds of Olives flourish in almost every part of the colony, and are very profitable. The Date Palm, Phœnix dactylifera, also grows well; a hundred trees are also growing well in Adelaide, and though fruits have formed, it is stated that they have not ripened. The reporter considers, however, that this will probably be obviated further north, where the climate is hotter, and suggests that the *employés* on the Overland Telegraph line should make experiments in planting the Date Palm. The white Mulberry grows splendidly in many places. The extensive planting of all these plants is recommended as a means of transforming some of the arid places in the north into oases, thereby increasing the production of the colony generally.—*Ibid.*

A New Cotton Plant.—Mr. A. A Luber, of Macon, Georgia, has (we quote from the *Times*) been experimenting for several years to hybridise the Cotton plant that grows wild in Florida [?] with the common Ochra, and he appears to have been at last successful. The new plant retains the Ochra stalk and the foliage of the Cotton. Its flower and fruit, however, are strikingly unlike either Cotton or Ochra. The plant has an average height of 2 feet, and each plant has only one bloom. This is a magnificent flower, very much like the great Magnolia in fragrance and equally as large. Like the bloom of the Cotton plant the flower is white for several days after it opens, after which it is first pale pink, and gradually assumes darker shades of this colour until it becomes red, when it drops, disclosing a large boll. For about ten days this boll resembles the Cotton boll, and then its growth suddenly increases until it reaches the size of a Cocoa-nut. The lint does not appear until this size is reached. Then its snowy threads begin to burst from the boll, but are securely held in place by the Ochra-like thorns or points that line the boll. Each boll is said to produce about 2 lb. of very long-stapled Cotton —superior to Sea Island Cotton [?]. There are no seeds in the lint—from four to six seeds, resembling those of Persimmon, being at the bottom of the boll. The new Cotton consequently, it is stated, needs no ginning, and it is thought will revolutionise the Cotton industry of the South. The Ochra, we may add, is known to botanists as Hibiscus or Abelmoschus esculentus, the pods of which are used to thicken soups, they being rich in mucilage. It is not many years since that a statement of the same kind was made with reference to a so-called hybrid Cotton raised in Egypt, between the Cotton gossypium herbaceum and the Bamia, or Ochro (see *Gardeners' Chronicle*, n. s., vii., p. 561, and vol. ix, 1879, p. 16); but we believe the hybrid character of the plant was not borne out, and the account given by the *Times* is assuredly not one that should be accepted without evidence. The size of the boll and capsule, and the quantity of Cotton as given are so large as to lead one to doubt very strongly.—*Ibid*

STORING POTATOES.—A cheap and efficient plan of storing Potatoes we have had in use about six years, and found it answer in every way; in fact, much better than the old plan of clamping them in the open ground as we used to do. We can examine them without trouble and in any weather. A description of this may be of use to some readers who have no cellar or frost-proof place in which to stow them. We had a hole dug in the tool shed about 6 feet long, 4 feet wide, and the same in depth, placing some rough boards round to keep the soil from falling in, the end boards fitting tight to keep the sides in their places. The top was covered with two old doors, auswering as a covering for the pit and a floor to the shed. We store about a ton of Potatoes every year, with a little straw on the top to keep the air from them. We have had them safe with the thermometer registering 20° of frost. We also find it an excellent place to keep our Dahlias in, also Beet or any roots that are injured by the frost. They keep as fresh and plump as when packed in sand.—H. E. M.—*Journal of Horticulture.*

A PAMPHLET on the FOREST AREAS IN EUROPE AND AMERICA AND PROBABLE FUTURE TIMBER SUPPLIES, by Dr.. Lyons, M.P., is just issued, and contains a large amount of important information in relation to this subject. Dr. Lyons has been engaged for two years, through the agency of the Foreign Office, in investigating the matter; but a large portion of inquiries in reference to Canada has not yet been completed. The concluding paragraph, in reference to the importance of the subject, is as follows:—"With every State in Europe and America alive to the urgent necessity of forest work, and with the example of the great forest system of India before us—not yet forty years under conservancy, but already controlling 60,000 to 70,000 squares miles of forest—shall these islands alone stand aloof from the great work of forest conservancy and extension? Out of 77,000,000 acres it is possible for England, Ireland, and Scotland to contribute, with advantage to their industries as well as their agriculture, something like £20,000,000 sterling per annum. The day her industries are paralysed by failure of timber, now within measurable distance of us, this Empire must descend from her high place amongst the nations."—*Journal of Horticulture.*

TURTLE OIL.—Some turtle oil from the Seychelles was recently presented to the Museum by Messrs. Wright, Layman and Umney, accompanied by the statement that it was used in that island as a substitute for cod liver oil in the treatment of consumption. On a previous occasion, some turtle oil from Jamaica had also been presented to the Museum by Messrs. Evans, Lescher and Evans, who informed me that it was esteemed as a cure for consumption, and asked for information concerning it. Both the oils are of a yellowish colour, and at ordinary temperatures in this country form a thick finely granular fluid, resembling in consistence olive oil which has partly congealed. According to Simmonds ('Commercial Products of the Sea,' p. 368) as much as ten gallons of oil are sometimes obtained from a single turtle of large size. He states, however, that the fat is exposed to the heat of the sun, in order to convert it into oil. There can be no doubt that the oil could be obtained in very large quantities if a demand should arise for it, since Mr. Brooks states that he would find no difficulty in supplying six thousand gallons per annum from the Seychelles alone. An animal oil so comparatively free from smell and taste and of fairly good keeping qualities, of which the supply is practically unlimited, should find many applications beside use in medicine. Its colour and non-drying properties render it admirably adapted for pomades, for which an animal oil is generally considered to be preferable to a vegetable one. *Jamaica Turtle Oil.*—Concerning this oil, I have only been able to learn, through a correspondent of Messrs. T. Christy and Co., that it is obtained from the flesh of the back of the turtle known in that island as the trunk turtle, which is supposed by Dr. Günther, of the British Museum, to be *Chelonia caouana*. Mr. Calderon states that "it is much used by the natives of the Tortola and Virgin Islands as a substitute for cod liver oil, and said to be more efficacious. In is also used as an alterative in syphilis, and is almost their only remedy for rheumatism, for which it is taken is ternally and used externally.' The sample I have received it not quite so palatable as that from the Seychelles.—*Pharmaceutical Journal.*

GIVING LIQUID MANURE.—"Never give liquid manure to a plant when the soil is dry, and never give food to a man when he is famishing." "Thinker" does not mean this, I dareasy; but it is what his advice about dry soils undoubtedly amounts to. I do not often water Peas, but in dry seasons I have had to do it, and as it is as easy to give liquid manure at such times as water I have poured farmyard manure, full strength, along the rows clear of the haulm, and then washed it in with the hose. The Peas were drooping with the drought when this was done, and the result was accelerated and better growth. I agree with all "Thinker" says about the danger of giving manure too strong; but in regard to dry soils I am, provided the manure is of the proper strength, a—NON-BELIEVER.—*Journal of Horticulture.*

EVERGREEN OAKS.—Having seen some letters in the *Field* on the subject of evergreen oaks (Quercus ilex), and the advantages of planting them for shelter, and having lately spent some time in the native country of that tree (Morocco), I think it worth mentioning how much the acorns are made use of as food in that land, both by the people themselves, and all animals, both wild and tame; enormous quantities of them are sold in the markets, and are really, I think, capital eating, superior to chesnuts or walnuts; the wild ducks eat them in such numbers that sometimes they are so gorged as to be almost unable to rise. The trees bear two varieties, one kind deliciously sweet, and another totally uneatable, and of a most acid and bitter taste, not easily got rid of. In appearance they are undistinguishable. The whole country seems to have been originally a forest of this tree, and in most uncultivated places is now a dense copse of this husk. Your correspondent mentions that these trees (Q. ilex) flourish splendidly in Devonshire, and ripens their acorns. I should much like to know if those so ripened are sweet and eatable as in Morocco. The trees grow splendidly in Ireland, but the acorns never ripen and seldom form. I have never seen the fruit brought to this country for sale, though I think it would be approved of. It is sold in Gibraltar, but those sold there are quite uneatable, apparently not the right variety.—DERG.—*Field.*

LINNEAN SOCIETY, November 6.—Mr. W. T. Thiselton Dyer exhibited the following plants and their products:—(1) *Vaccinium arctostaphylus*, from which the Trebizonde tea ("Thé-du-Bu-Dagh") is prepared at Amassia and Tokat. The tea has a pleasant odour, but a somewhat harsh taste when drunk. (2) *Pueraria Thunbergiana*, specimens of this Corean plant and of the cloth made from it. (3) *Pachyrhyza sinensis*, with the native name of "Kopoo," a leguminous plant from the fibres of which the yellow and more expensive summer cloth is made.—Mr. Thos. Christy showed and made remarks on a specimen of *Kola acuminata*.—Mr. R. A. Rolfe afterwards exhibited examples of British oak-galls produced by Cynipidean insects of the genus *Neuroterus*. These were the silk-button gall formed by *N. numismatis*, the globose gall produced by *N. ostreus*, the smooth-spangle gall formed by *N. fumipennis*, the scarce-spangle gall formed by *N. laeviusculus*, and the common spangle gall produced by *N. lenticularis*, as also a purple variety of the latter gall. He stated that the plan and details of the galls depend on the nature of the irritating fluid deposited by the insect; but on the other hand the different species of oak seem to have an influence in determining certain variations as to colour, and, it may be, general growth, of the gal's. A collection of plants ma le in Timor Laut by Henry O. Forbes. Thereiu a short account is given of the nature of the islands and of the general character of the vegetation, after which comes a technical list of about eighty plants.—Prof. Oliver adds a note that, "This collection, so far as it goes, is made up in great part of the more widely diffused species of the Indian Archipelago. The most interesting plants appear to be: one in fruit only, referred to the meliaceous genus *Owenia*, probably *O. cerasifera*, Muell., of Queensland; a fine *Mucuna*, of the section Stigolobium; a *Selaybrea*, an araliaceous genus hitherto only received from New Caledonia, and a fruit of possibly a *Strombosia*. Mr. Forbes himself is inclined to regard the Timor Laut flora and fauna as having affinities with the Moluccan (Amboina) region.—*Nature.*

COL. E. MONEYS LETTERS ON TEA.

No. I.

[We have arranged for a monthly letter from the Prize Essayist on Tea. The following is the first of the series.—Ed.]

East India Club, St. James' Square, London, S. W.,
Feb. 20th, 1885.

The loss of S. S. "Justitia," wrecked off the coast of Ceylon, with 8,000 chests of Indian Tea, has somewhat helped to raise prices. The market is decidedly better. I incline further to the belief, looking to the figures, Imports, Deliveries and Stocks, that we shall see much better yet. Late deliveries are in excess of anything previously realized. The war, which, in the opinion of some, would affect prices so materially, has not done so up to this, but, should it continue, it is quite on the cards that it may do so, eventually, to an extent not dreamt of today.

Will Indian Tea (I include Ceylon) be *the* tea of the future, as some, prophecy? He would be a bold man who said "Yes" decidedly; equally bold he who denied it. What are the figures for the last 20 years? I give them here in pounds.—

Year.	China.	Indian (Ceylon included).	Total.	Percentage. China.	Indian.
1864	85,704,000	2,796,000	88,500,000	97	3
1874	118,896,000	18,528,000	137,424,000	87	13
1884	110,880,000	64,212,000	175,092,000	63	37

We have here three decades. Whereas Indian tea was only 3 per cent of the total consumption in Great Britain in 1864, it became 13 in 1874, and 37 in 1884. The above shows also, that, in the last decade, China tea has diminished by 8 million, India has increased by 46 million! We now supply more than one-third of the total consumption. How long will it be before we give half? I may be wrong, but I would back my opinion, that, within five years of this time, the excess, if any, will be on the side of Indian and Ceylon.

How enormously, besides, does the total consumption increase. What was 88½ million, in 1864 is close on the 176 million in 1884, that is to say the consumption has doubled in 20 years. Will it double again in the next twenty? Certainly not, I say, but it *will* increase largely, and if Indian planters are wise and lay on their oars, if Ceylon extends gradually and not in the mad way it is doing now, we may yet see the day when demand will overtake supply, and decent prices result. Not the prices that ruled formerly, *that* can never be, but still prices considerably ahead of what are quoted now.

One great cause of low prices is due to the way the home market is flooded at particular seasons. Could the supply be more evenly distributed throughout the year, a great advantage to producers would result. It is early I admit, to urge this point on Ceylon planters today, for the quantity you supply now, as compared with India, is small, under 1½ million pounds I see from 1st June to end of December last year. The real help, if help do come, must be from India. It is a very difficult question how it is to be done, so many and conflicting interests are at stake, and Indian planters are not wise enough yet to act unanimously. Still no harm in ventilating the subject thus early both in Ceylon and India, with a view to joint action eventually.

Looking at it from an Indian point of view, it is sad for India that Ceylon has proved such a good tea-field. But though, doubtless, your yield is very slarge per acre, and the quality of the tea very good, there is one point not proved yet, which Ceylon planters should not shut their eyes to. In India they give the plant rest, a holiday for three or four months, less in the plains, more in the hills, and it may be, nay it is probable, this rest is a necessity. In Ceylon you pick more or less all the year round. Is this wise? Will the tea-plant stand it? I do not say it will *not*. Manure may do much to mitigate this evil. But the chance of a collapse should not be overlooked, and were I a tea-planter in Ceylon today, I would, in spite of the climate which enabled me to pick all the year round, not do so.

Take it all in all, during this last year, 1884, I must admit that Ceylon has in a measure beat India in quality. Will it always do so? Is there any reason why it should? I think not. The soil is certainly no better with you. The climate may be more forcing, but that does not argue better tea. If anything in India, the least forcing climates produce the best though weaker teas. In my opinion the excellence of Ceylon teas is, in a measure, due to the fact that the gardens there are young. I mean that a tea plant, say four years old, produces *cæteris paribus* better tea than an old bush.

There is yet another point about Ceylon I would notice, but I will not do so today. I await further information. Do not you or any of your readers, be they in India or Ceylon, imagine I wish to decry your island and throw doubts on its success in the tea-line. I quite believe it is destined to be a very serious rival to India, and more than that I hope so (why, it would be out of place to state he.e). But I think Ceylon is going too fast ahead, and its eventual success will not be diminished, nay increased, by caution.

There is no doubt Ceylon *has* achieved a great success, and that its future as regards the tea industry seems a bright one. I quite believe it will be so, but the "tide taken at the flood" must be taken reasonably, and from all I hear this is not the case. Large areas quickly planted are not always planted well. How many gardens, good gardens, in India have failed financially, owing to hasty and unadvised extensions. Again and again have I heard planters regret they were not satisfied with a reasonable area, in any case satisfied until the reasonable area paid, and put them in funds for increased cultivation. They regretted their mistake when too late; let Ceylon planters be wise and gain experience at the expense of others, and not at their own cost.

You have asked me to write occasionally on tea matters to your paper. I shall be glad to do so and study the interests of Ceylon Teas. Both in the "Lane" and outside, I shall often hear much that your planters ought to know. But I shall always write honestly, if even what I write is not welcome.

Do you know anything in Ceylon about "Blackman's Air-propeller" which was exhibited at the Calcutta Exhibition? We have tea manufacturing machines of many kinds, but in my opinion a leaf withering machine has yet to be invented. I think this Air-propeller may possibly solve the problem. *Why*, I think so would take a couple of columns to explain, and would then be only a repetition of what I wrote in 1884 to the *Tea Gazette*.* It would, I am sure interest your readers if you sent for and reproduced the article.† I may add that I think now, as I wrote then regarding the probable advantages of the Air-propeller to inaugurate a new system of leaf withering. We all know what an important feature in tea manufacture withering is, and how difficult it is to carry it out successfully in wet weather. We also all know (though some inventors assert the contrary) that no tea-drying machine will do the withering work satisfactorily. We do not know yet what the success of the plan I have sketched in the article aforesaid would be, but I am sure the idea deserves attention, and I believe

* The article appeared in the issue of 18th April 1884.
† We copied a portion at the time.—Ed.

the Blackman's Air-propeller Company would give reasonable help to any planter inclined to work it out. Let any such apply to me and I will give what assistance I can. EDWARD MONEY.

JAVA GOVERNMENT CINCHONA PLANTATIONS.

REPORT ON THE GOVERNMENT CINCHONA ENTERPRIZE IN JAVA FOR THE FOURTH QUARTER 1884.

(*Translated for the "Ceylon Observer."*)

The beginning of this quarter was marked by many dry days. In November many heavy showers of rain fell, whilst in December again many dry days were registered. The supply of labor was very large: in fact, the force available could not always be utilized in connection with the funds set apart for the cinchona enterprize. The gathering of bark was, so far as the weather permitted, carried on uninterruptedly. As in the previous quarter so also in this pretty large quantities of Ledgeriana slivers were gathered. Important experiments were made with the scraping of Ledgerianas and officinalis, which deserve mention. As has already been noticed, the middle and the end of the east monsoon are the best period for showing off the bark. In order to dispense with covering, the trees were shaved over only half their circumference, so that, for example, one year the south half, the near the north half, is subjected to the operation. The question was raised, however, whether the trees might not yield two crops of bark in one year, without covering, by means of scraping. The experiment was made on a large scale, and the result has so far fully answered expectations under the following conditions:— (1) that a thorough working of the soil accompany the repeated shaving; (2) that between the two croppings a period of at least 2½ months elapse. If both conditions be not carried out the trees suffer, especially after the second operation, to such an extent that they soon assume a sickly appearance. The question has now to be solved, whether the trees will be able to bear the repeated operation, as well as whether the composition of the renewed bark warrants the abovementioned method of harvesting. The graft plantations of known, analysed trees at Tirtasari ought during 1885 to yield the necessary material for chemical investigations. The crop of 1884 comprized about 350,000 Amst. pound. Of this by Dec. 31st 314,387 lb. had been dispatched to Batavia, whilst 2,263 lb. was reserved for the local military medical service. On 15th Oct. the second half of the product of the crop of 1883 was sold by public auction at Amsterdam. The prices obtained were considerably less than those fetched at the sale of 19th July. The highest price was paid for a lot of Ledgeriana slivers, which fetched as high as *f*2·19 per half kilogram. The lowest price was given for dust of C. Josephiana, which bark realized only *f*0·05 to *f*0·32 per half kilo. As the harvesting of this most inferior bark no longer pays the cost of packing and dispatch, the product of young branches and twigs will in future not be gathered.* Good prices were paid for officinalis barks. These varied from *f*1·76 per half kilo for root bark to *f*0·85 for dust. The net result of the sale was about *f*115,000, with an average price of *f*0·69⅝ per half kilo. A beginning was made in November with the planting out, which work is, so far as the weather permits, being carried on uninterruptedly. The plentiful rains after the severe drought in the last monsoon had a favorable influence on the growth of the plantations, whilst the plants in the nurseries also developed vigorously and will yield a good supply for planting in the first quarter of 1885. Shortly after the setting in of the rains the *Helopeltis Antonii* again appeared in full force, especially at Tjinjiroean and Tirtasari. By a timely catching and killing of the insects the damage done was very small.* The sale of cinchona seed at three auctions held during the quarter brought in *f*4,770, whilst at two sales of grafts 360 of these were sold for *f*3,600. By Government order No. 4/*c* of 28th Dec. 1884 it was resolved that in future the Ledgeriana grafts and cinchona seed not required for the Government enterprize should be sold by public auction without limit.

VAN ROMUNDE,
Director, Govt. Cinchona Enterprize.

Bandoeng, 5th Jan. 1885.

* *N. B.*—Ed.

ARECANUT CULTIVATION IN CEYLON.

We call attention to the useful information on this subject conveyed by Mr. Borron in his letter published on page 791. Although, as the writer says, there is still a good deal of special knowledge only to be attained at the cost of time or money, still enough is told us to show that the European planter might do worse than turn his attention to the areca palm. Six years' waiting for a crop is the chief drawback; but this is so much less than in the case of coconuts, although the areca palm is almost equally long lived, that it ought rather to encourage than prevent the planting of arecas. Mr. Borron may be depended on as a careful estimator, and his calculation of an average return of 20 cents per tree per annum, with trees planted 10 by 10 feet is eminently moderate and safe. That would make 435 trees and a gross return of R87 per acre. From this would have to be deducted the cost of upkeep, watching and harvesting the fruit. After six years' growth, the cost of maintenance would be very slight we should say, although, of course, such works as digging and manuring would, if carried on, cost money, but they should bring in a due return if judiciously undertaken. Watching and gathering and selling the nuts would therefore seem practically to be the chief items, on the debit side. We suppose, then, that a net annual return of R60 per acre might safely be counted on (where other products shared the attention of the Superintendent) and this steadily coming in from 100 or even 40 acres of arecanuts is a source of income not to be despised. Fifty rupees per acre was mentioned the other day as the net return from average well-managed coconut plantations. So that arecas must be deemed more profitable.

We are aware that far more sanguine estimates have been put forward by a planter in the south of the island (vide the *Tropical Agriculturist* for April 1883); but these were based on the planting of 1,200 trees per acre, such trees and still yielding at the rate of 300 nuts per tree! The result was to be a nett profit of R140—the expenditure however costing R100 per acre. We need scarcely say that Mr. Borron's calculation seems the safe practical one, and indeed it is based on actual experience over some 40 acres planted by him and in bearing. There may, however, be such a difference between the Lower Matale and Udagama districts as to warrant closer planting, but not surely to the extent of crowding 1,200 instead of 435 palms into the acre.

Anyhow, arecanut planting is worthy of more general attention, and as a very suitable addition to other products on plantations under 2,500 feet elevation with a decent soil and a suitable rainfall, we strongly recommend it. In the Kegalla, Awisawella, Yatiyantota and Kalutara districts, and indeed around Gampola and Nawalapitiya and perhaps Kandy, there ought to be room for putting in fields of areca palms as still another product, and one of the least troublesome, for the planter to add to his reserve list.

MANURING COFFEE.—A coffee proprietor writes:— "I am so pleased with the result of ½ lb. of manure to a tree, that I have on its way a shipment of manure from a London firm who I do not think have ever sent manure before to Ceylon. I have not lost heart yet in coffee (while new products receive attention). We cannot help the effect of wars and rumours of wars, nor the depression which is so universal, and I think that patience and steady work must eventually meet with reward.

PLANTING TOPICS IN CEYLON AND S. INDIA:

THE REIGN OF TEA IN PLACE OF COFFEE—A FULFILLED PROPHECY—A GLOWING PICTURE—DIFFERENCES BETWEEN CEYLON AND INDIA—ADVANTAGES OF INDIA—TRUE HAPPINESS—CARDAMOMS—CEYLON IN NEED OF ANNEXATION TO INDIA!—CACAO—CONCENTRATING ONE'S ENERGIES—THE P. A. MEETING—THE OLD BADULLA MEETINGS—SCIENTISTS IN CEYLON.

A hearty greeting to the "Old Rag" and my old Ceylon friends for 1885. This year's first morning sun beams on a brighter scene than has been the case in Ceylon for many a year. It sees something like the old musters again; something like the old stir and bustle in the erst abandoned buildings; and a new odour emanates from the stores,—it is not the sugary scent of cherry-skins, nor the tan-pit smell of those skins after they have lain for some time, but it is the malty rich perfume of tea-leaf as it is crushed, fermented and fired by new-fangled machinery. And this 1885 sun looks down and sees the day brighter, and the doings of men develop into full energy on those mountain gardens in Ceylon. Each well-known portly form in easy tweed and Ellwood hat treads with a lighter step because his heart has begun to beat with hope instead of being crushed with dark despair. He has a hard tough plant that seems to suit the climate, so that the old struggles will not likely be repeated. Coffee is but exotic, so is cinchona; but in tea, as that old Sinhalese in a late *Observer* is described as saying to the peripatetic *V. A.* prospecting for tea in Harper's old abandoned place, "Tea is just the same as a jungle plant, and holds its own even when abandoned with the native weeds and thorns." As Mr. Elliot of Mysore said many years ago in your office: "It seems to me that Ceylon is eminently favourable for the growth of leaf." Why, old "Cattle-plague" laid down the law to R B. T. that his favourite coffee would have its nose put out of joint by tea. I heard him. That was on a moonlight night in Dumbara in 1874. You have a very far-seeing man in Dimbula. I won't tell his name; but he prophesied and the prophecy has been wonderfully fulfilled.

Well, go on and prosper! Let chest upon chest of balmy fragrant leaf cross the swelling deep and scatter over hearths and homes of merrie England; let the name thereof become known among the merchants of the West; let it fill with despair the Celestial conservatives; let it start the silent wheels, rub bright the powerful shafts and re-kindle the furnaces of the noble mills of Colombo*; let it brighten the dull eye, whether of the hardworked Colombo agent, the estate proprietor, the salaried manager; let it draw like a magnet those sons that have left the island's shores in sore depression, and attract new blood, new energy, as well as restore animation in the old blood, the old energy.

I think Ceylon has done right. Men here ask why new seed was not tried, but these men have not themselves been gradually led into a quicksand and slowly realized their position. Planters in India are proud men if they can get 3 or 4 cwt. per acre, and spend R40 to R60 per acre. They use up a large proportion of their resources and energy in combatting a sun like fire and a heaven like brass, in enduring months of cloudless heat, and cold blighting winds, in lapsing into the opposite extreme and getting mildewed by continued steady monsoon rains. Well, you see Nature keeps them in prescribed limits and they can't help themselves. "Hitherto shalt thou come and *no* farther," is the law in Mysore. In Ceylon, the climate, the soil, the *latitude* in many senses admits of urgent enterprize being pushed to undue limits, and then comes the terrible recoil. There was an outrage committed on nature here to start with. The native said, coffee wanted a *screen* (not an *umbrella*), a light venetian-blind (I don't mean that the native really mentioned these blinds but their *equivalent* in Canarese), to break the solid mass of sun-rays and weather and distribute their power. English planters pointed to Ceylon, and down went the forest giants. The coffee throve grandly, and great was the joy in the land. Well, Nature's agent in Mysore was more honest though more abrupt than her agent in Ceylon. She tripped up the transgressors at once. The borer simply left them with bare soil—bare of coffee as well as of trees. Stunned by this sudden and severe lesson the planters here have struggled on, and now find the prices reach that low limit where confidence becomes very shaky and hopes are dull. Now there is enough to keep a man yet; crops have not disappeared, and labour costs just half what it does in Ceylon, so that prices have not the same effect at the same range. But the outlook, what is it? Is coffee to be a favourite European enterprize? or will it gradually die with the present cultivators? The merits of the bean are but scantily known, and the way to develop them is difficult. That is not the case with tea and cocoa, and beer is always handy to the working man. I believe that coffee is going out of fashion and the market has reached its normal state after the ferment of the Ceylon excitement. It won't go lower, and if men can make their estates crop fairly they have a cheap enough labour market here. Not so in Ceylon, so let coffee die, and long may tea fill your stores and purses. Good luck to Ceylon for 1885!

But a word for these coffee planters here. Ceylon men can't equal the extreme care and pains they take on many places here. A Ceylon man is struck with this. The cheapness of labor and the absence of competition, leaf-disease, V. A.'s, Colombo agents and the telegraph wire, as well as the fatherly attentions of a British Governor and his satellites being conspicuous it seems possible for a man to fulfil his calling and live a pleasant life without his dreams being disturbed by "bumper crops." "Give me neither poverty nor riches," is the true happy desire. When tea has run its course and we are all removed from the scenes of toil and trouble, some enterprizing men may again start coffee in Ceylon, but it will not be till the world has got a long way into the 20th century. In the meantime, I need not discuss coffee more in your columns. It is dangerous to refer to the old love when the charms of the new are blushing fresh and fondly. I thus drop a tear and heave a sigh for the memory of many a happy day in years gone by.

You are making terrible progress with Cardamoms. These Ceylon fellows are at it again spoiling every market they touch. They have done harm enough with coffee and cinchona, and here they are with cardamoms. I suppose they will finish up by doing the same for Northern India as they have for Southern India. Dufferin should "annex" it, or hand it over to the Germans who want colonies. Bismarck would make a grand V. A. Any amount of sacking and blood and thunder. The worst of it is that the more Ceylon is beaten, the better she comes up to the scratch; so we Indian fellows soon won't have a chance left save to struggle on with a ruined market as the coffee planters have to do. That big drought on the top of the cardamoms in Ceylon raised our spirits a bit. You seem to have it all your own way with Cacao as far as the East is concerned; but I have no doubt the circulation of the *Tropical* has increased in the West Indies as these poor fellows

* Unfortunately this can only pass as poetry: tea does not benefit the poor Colombo millowners a cent.—Ed.

want to know the worst about their bread and butter. Anyhow it's a comfort to think that tea may take away attention from cardamoms. I really would advise you to go *in for tea*. Don't bother with cardamoms when you have such a fine thing on. There is nothing like CONCENTRATING YOUR ENERGIES (printer! rise to the occasion)! ABERDONENSIS.

P. S.—The account of the P. A. meeting to hand. The Chairman being an unpractical man, the proceedings take that turn invariably, I think. Mr. Talbot, now that he has got Peradeniya as a breakfasting station, weeps over his whisky. A practical man would buy up a stock before the price rises. If Ceylon be a "paternal" nt, Governmethe planters certainly are rather assertive children. What fun all the talk about not being asked whether or not they objected to be taxed before Government passed the obnoxious ordinances. Elphinstone's manly, though rather incoherent, defence of the Governor shows that the Chairman and Talbot had not it all their own way. The whole meeting was a mistake. A public meeting should have been called, and then a variety of eloquence might have been experienced. I see old Sproule of Badulla has come to Kandy. He was the planter's proctor and a popular genial man. He must have made comparisons between the old Badulla meetings where James Uva was Chairman, and George Wharton Brown Secretary, and the other fellows came to fill up the room, make calls, do some shopping, and, after cricket, gallop home over the paddy-fields. What a lot of Badulla men have gone since then! Hinck the comedian, Linton the patriarch, Geordie Morris the *ancient* partiarch, Old Wood of the old school, Watt and his long beard, and many others are all gone to their old home! Ceylon men ought to be very scientific by this time. First there was Phipson and his surface manuring. Then there came Moutclar, Morris, Ward, Trimen, Schrottky, Storck, and "W." Then we had a lot of technicalities about cambium and alkaloids and sulphates; and now comes tea, and the talk takes an engineering turn, and we hear all about rollers and twisters and firers. Well done, Ceylon, the undaunted and brave!

CHANKS AS ALLEGED DESTROYERS OF PEARL SHELLS.

The following article, interesting to us in Ceylon, is from the *Pioneer*:—

Mr. Thomas, the veteran fisherman of the Madras Presidency, has recently been investigating the pearl fisheries of Tuticorin with a view to their future improvement. His report will no doubt be read by all lovers of the pearl, nor would it be difficult to interest the ladies of India on behalf of the oyster in which it is embedded. Mr. Thomas, however, has acted with doubtful wisdom in attempting to vindicate the "chank" from the charge of enmity to the pearl-oyster which has long been brought against him. The "chank" (*Turbinella pyrecm*) it may be stated is another shell-fish which is often found near oyster-beds and is regularly fished on account of its beautiful shell. He is strongly suspected of eating the pearl-oyster, and so strong indeed is the suspicion that the Secretary of State once ordered his extermination. This terrible decision has not been thoroughly carried out, and the poor "chank" has at last happily found so able an advocate as Mr. Thomas to say a good word for him. The evidence against him is partly circumstantial and partly as to identity, and it is no doubt exceedingly damaging to the general character of the "chank." In a fox-hunting country vermin are every day killed on much less proof. In the first place the "chank" is carnivorous. There is no doubt as to this; his teeth betray him. In the second place the "chank" has a near cousin, "the elephant chank," who has been found in such a position relatively to a dead oyster as to make the conclusion that this relativity was the cause of the oyster's demise unavoidable. If a shell-fish is found curled round the corpse of another, and the shell of the corpse is perforated in a vital part, and the perforation could have been caused by the lancet tongue of the circumjacent mollusc, any jury would give a verdict of "wilful murder" against the latter. And such is the case against the "elephant chank." That the chank common should suffer from the character of his elephant cousin is not surprising. But more than this, there is evidence that the chank common has been caught in the act of eating an oyster. This shows that he has no moral objection to oyster-murder, and the only question is whether he is in a position to commit it. Mr. Thomas argues that the "chank" common is without the lancet tongue necessary to perforate the oyster. He cannot get at the delicacy while it lives, and must wait till it opens in the act of death. He is the jackal or the ghoul of the pearl-oyster bed, but not the murderer of living oysters. Furthermore Mr. Thomas urges that the oyster's home is the rock and the chank's home the adjoining sand: that the chank rarely ever leaves his home, and that the pearl-oyster need be in no dread as long as he sticks to his own quarters. But Mr. Thomas' vindication of the "chank" is by no means satisfactory, as the admissions he has to make in the course of the defence are extremely damaging to his client's reputaion. Were we on our trial for homicide, we should prefer the mercy of the Judge to the advocacy of the First Member of the Madras Revenue Board.

THE VALUE OF THE *T. A.* TO CEYLON ESTATE OWNERS.—A correspondent writes:—"Teldeniya, 20th March.—I think proprietors should supply every tea estate with the *T. A.* The information in it with regard to everything in connection with tea &c. is invaluable: it would pay its value over and over again. Owners of estates should not leave it to hard-up superintendents to take it in."

TEA GARDEN COMPANIES' REPORT.—The Managing Agents of the Singell Tea Co., La., have issued their Report for last season's operations made up to 31st December; the profit and loss account shows a profit of R15,771-9-2 (inclusive of R1,635-11-1 brought forward from last year), which is equivalent to 2½ per cent on the capital of the Company. The total outturn for 1884 was 215,800lb the whole of which was sold in Calcutta at an average of annas 8·76 per lb nett. The crops suffered severely both in quantity and quality from the last two successive dry seasons; 1883 was remarkable for its short rainfall, but 1884 showed a fall of 22 inches less than that, and 60 inches below the usual average on the estate; the Manager however reports the Garden in fine order, and no particular loss of soil from wash had been experienced. —*Indian Planters' Gazette.*

KADUGANNAWA, 20th March.—At last, after a very long and severe drought, we have had refreshing rains, but, like Oliver Twist, we are unsatisfied and want more. Wells are still dry, and streams nowhere; but the face of Nature is cleaner and fresher, grass is sprouting, blossom coming out, and man and beast are happier for the pleasant change. Coffee where there is wood is throwing out a fair blossom, but, alas! there is not much vitality left in old King Arabica, and in this district, I fear, his days are numbered. Leaf-disease appears to have succumbed to the dry weather in the meantime, and there is not much black bug, but the mischief has been done, and done irretrievably. Cacao has stood the drought very well, and is blossoming. The "fly" can be kept in check, and squirrels may in a measure be frightened by powder and shot. The villagers are busy harvesting their grain, and they appear fairly well satisfied, but there has been a good deal of distress amongst them.

Correspondence.

To the Editor of the "Ceylon Observer."

JUTE CULTIVATION.

Walkerston, Mackay, 1st Jan. 1885.

Sir,—Would you kindly through the medium of your paper give myself and a few others here interested an account of the cultivation of jute?

1st. The class of soil most suitable, how wrought to give the largest return?

2nd. How is the crop dealt with as it progresses?

3rd. Is the crop raised from seed, or how?

4th. What is about the average weight of crop per acre, and the average value per ton?

5th. How is the crop dealt with when cut down? and what are the symptoms when ready for cutting?

If you would kindly answer these questions, and give us any other particulars, necessary for the starting of jute cultivation which we purpose doing here if your answers should so warrant us.

GEORGE K. AITKEN.

[Our correspondent will find some information on jute cultivation and preparation in the first volume of the *Tropical Agriculturist*.—Ed.]

THE AMERICAN EVAPORATOR.

Vineland, N. J., U. S. A., 5th Jan. 1885.

Gentlemen,—Accept my especial thanks for the lengthy and favourable notice of the "American" represented in Ceylon by Messrs. W. H. Davies & Co. on my behalf. On the part of my Company I convey their thanks also, as they especially appreciate the courtesy if only from the fact that it emanates from "Britishers," and it took some pains to assure them on my part that no feeling of opposition would be found among English planters to American inventions, as they at first feared that prejudice would exist on that score. As an Englishman, it is difficult to understand how such an idea can exist; but, nevertheless so it is among many here, who only look on "J. B." as a hereditary foe.

By this mail I addressed Messrs. W. H. Davies & Co., asking them to request you kindly to insert a correction on some points, as a justice to the "American," notably that of *cost*. A reference to the advertisement in the *Agriculturist* shows our No. 3 as priced in Colombo at R750. Davidson's No. 3 "Sirocco" is priced in England at £90. Our quotation here for No. 3 is $250; and *experientia docet*, for we intend landing our machines in Ceylon at a much lower rate of freight than we did in our initial shipments.

From what I see of No. 3 "Sirocco," I agree with you that, for *work* comparison, it is *the* one to compete in trial against "American" No. 3, but for *price* the parallel is wanting, and I trust you kindly will note this when commenting on a future competition.

You evidently understand that the "American" is not an experiment or new affair, as it has a record of 17 years and sales of over 9,000 machines and has obtained over 400 medals, diplomas and awards, as *the* drier par excellence in this country. I obtained information of many since my arrival in America, but they hold no rank as evaporators when pitted against the "American." We will await the result of a practical trial of the "American" (N3) against a "Sirocco" No. 3 with interest, and all we ask is a "fair field and no favour, may the best win."

Tea appears to be indeed "booming" in Ceylon, and I almost now wish I had stayed there on my way home from Assam, but my wife and children being in England ahead of me prevented me.

Wishing you the compliments of the season, I am, gentlemen, yours faithfully,

VICTOR M. HOLLINSWORTH.

Colombo, 5th Jan. 1884.

One or two minor defects which however do not materially interfere with the drying process should be remedied at once, and these are the unprotected wood of that part of the trunk resting on the stove—this should be cased in iron both inside and out—and the close proximity of the funnel to the trunk, which should at least run two feet away from the stove before it points upwards, as in its present position it is likely to char the wood when the former becomes red-hot through the fierce fire employed in tea drying. The construction of the stove leaves nothing to be desired.

Blackstone, 12th Jan. 1885.

Messrs. W. H. Davies & Co., Colombo.

Dear Sirs,—I have made several experiments with the fruit evaporator No. 2 forwarded to this estate for my report thereon, and I come to the conclusion that it would answer as a tea drier, if it is slightly altered. I have compared its work also occasionally with that of the sirocco No. 1 in use here, when such comparison could be fairly instituted, seeing that the No. 2 evaporator is a small one of its kind and the siroceo a no ordinary stove.

At the first two or three trials, the results, as you may well expect, were not satisfactory, which should be ascribed less to the defects in the drier than to the fact that there were difficulties to overcome in converting into a new use an instrument originally designed for a far coarser operation than tea making. Even a strict adherence to the instructions were not expected to guarantee success.

On the 30th ultimo I had the good fortune to have the kind assistance of Messrs. Armstrong of Rookwood, J. A. Campbell of Waltrim, T. Scovell of Adam's Peak, P. R. Shand of Coolhawn, and A. Scovell of Strathellie. I can hardly say that the results were satisfactory. There was altogether such a want of uniformity on the occasion as to lead me to write to you my first letter, in which I said the results were discouraging. After one or two trials made again, I wrote to you not to publish my first till I experimented further. I have now come to the conclusion that the admirably contrived little stove and the advantages of the inclined flue can be turned to good account. I remember Mr. Armstrong on the first occasion calling my attention to the draft at the upper end of flue and saying: "Why, the heat here seems greater than in the 'sirocco,'" and he was right. And this is just what I have now to point out as a principal fault in the evaporator as at present designed.

The temperature was so high at this point simply because it did not take up enough of the moisture from the "roll" in its passage, to make quick work of the firing. And now I came to the defects in the drier which you ask me to point out, in order that you may forward my report to the makers.

The principal fault is that a large proportion of the hot air is permitted to pass between and above the trays, every breath of which can easily be utilized, and should be, before the evaporator can be called an unqualified success. If I may suggest, I think, that, by covering the upper end of the inclined flue and opening the top all along, the air can be made to pass through the trays.

The partition between the upper and lower compartment should be removed, I think, and there be left but one compartment with strips of wood running along the sides, for the trays to slide upon, the upper independently of the lower set. Over the stove an iron plate in a line with the lower trays, or an inch or two below, will turn the air into the flue under the trays. It may be remarked, that when thus altered and modified, the evaporator would bear a strong general resemblance to the new "sirocco." But one cannot help saying that the new "sirocco" bears a very strong—I had almost said significant—general resemblance to the older evaporator flue. The point of difference would lie in the one being horizontal and the other inclined, and it is the inclined flue that is protected by a patent in the evaporator. Then, as regards the dropping of the tips (pekoe tips) into the trunk and being left abandoned there till the end of the day's work, by simply nailing fine wire gauze, or even tray cloth, to the bottom of the trays, which, you will observe, have wood about two inches deep on the sides, the tips can be made to travel along with the trays and taken out with the tea.

Stove.—The stove should be a little more substantially built.

In conclusion I may add, that, if after due experiment the above is found to answer, and I have very little doubt that it would not, I would suggest your arranging to import only the stoves and having the flues manufactured in Ceylon on designs sent out by the makers, wood and labour being cheap in Ceylon. It would enable you to supply small gardens (and maybe larger ones too) with a cheap and efficient drier.—I remain, dear sirs, yours faithfully,

(Signed) Jas. H. Barber.

RESPECTING CINCHONA TREES RICH IN ALKALOIDS.

The Scottish Trust and Loan Company of Ceylon, Ld., London, 22nd January 1885.

Dear Sir,—I enclose some correspondence that has taken place regarding cinchonidine as it appear in bark.

It is worth the attention of planters to ascertain from observation—when the bark of a tree, by analysis showing a very large percentage of cinchonidine and not much sulphate of quinine, when said bark becomes renewed and its analysis shows a large percentage of sulphate of quinine and a decrease in the cinchonidine in proportion—whether such trees should not be closely watched and trees of this description highly prized.

I have already drawn Mr. G. H. D. Elphinstone's attention to this in reference to the Stair cinchona and also other estates in which we are interested. —I am, dear sir, yours faithfully,

THOMAS DICKSON.

38, Mincing Lane, London, 16th Jan. 1885.

T. Dickson, Esq.

Dear Sir,—In accordance with your request for information respecting the influence of cultivation and renewal upon the yield of alkaloids in cinchona bark, we now send you a paper containing the results of a number of analyses made by Dr. Paul to elucidate this particular point.

In addition we may mention that Dr. Paul had some time ago an opportunity of examining a sample of bark—succirubra—where original and renewed bark were associated together on the same quills, and the results of analysis were as follows:—

	Original bark per cent.	Renewed bark. per cent.
Quinine ...	1·31	1·74
Cinchonidine ...	1·82	1·94
Cinchonine ...	1·86	1·14

If there is any further way in which we can be of assistance, we shall be happy to do so on hearing from you.—We are, dear sir, yours faithfully,

Patry & Pasteur

[The table referred to, with the appended remarks, was given on pages 718-19 of the *Tropical Agriculturist*, Vol. III.—Ed.]

MR. ROBERT CROSS ON THE TRUE CINCHONAS AND RUBBERS.

No. 19, Cramond, Near Edinburgh, 6th Feb. 1885.

Sir,—Respecting your remarks on my communication which appeared in your journal of the 18th of last October suggesting a full description of the real red bark *cinchona* tree, I may state in reply that I consider the fullest details which could be written down would not suffice always to lead to its recognition when growing among spurious sorts, some of which it often resembles. This is owing to the fact that at different elevations and with varied aspects and conditions each species of *cinchona* when under cultivation presents a surprising multitude of modifications and types. I do not know how far a treatise with plates would go in this matter. Your suggestion of importing a collection of red bark plants into Ceylon from South America goes no doubt to the root of the question, though for the performance of such a duty it would be necessary for one to proceed personally to the native forests of the tree to collect plants, a course which would require a special contract as otherwise no one could expect to recoup themselves solely by the sale of a few hundreds of plants imported from their native habitat. Such a course, however, would be well worth all the trouble and expense it would cost, as it would insure a stock of the real original red bark plant besides clearing up the doubts entertained by some on the subject. If the cinchona plantations in Ceylon were mine, I would go over the whole of them—up one row and down another—and root out every spurious tree or plant of inferior species. It must be remembered that there are several inferior sorts besides the Huanuco bark scattered throughout the plantations in the East. I would then form small detached plantations of each species in a favourable locality solely for the production of seed. This course would prevent any jumbling in the future besides being a source where planters could obtain supplies of seeds of all the really good commercial sorts. If proper sites are chosen, and if due attention is paid to the young plants until they attain to some height, then a moderately sized plantation of such a sort as the real red cinchona ought in a very limited number of years to be an ample fortune for anyone. There are some important points to be looked to, not involving it is true extra expenditure, but which embrace various things during the period of growth and until the bark from the tree is ready for the bale; and these various points all cinchona planters should thoroughly master and understand, or they should be taught them. There is not the least doubt that with *good sorts* it is perfectly possible to steadily produce bark from the one end of a plantation to the other containing from 8 to 10 per cent of sulphate of quinine. Planters ought to learn to do this with as much certainty as they could boil a potful of potatoes. Otherwise a planter's position must always be like that of one groping in the dark for an object in some uncertain place. I have here referred to the red cinchona, but let no one imagine that in doing so I exclude "crown," a sort which I am persuaded, if properly handled, would be a doughty tree to beat. Of the analysis of barks of this species by Mr. David Howard already published in your journal, it will be observed that one sample gave 12·30 of sulphate of quinine; but I am quite satisfied that this is not the highest point the tree could attain to. Planters should endeavour to recognize the different varieties of each good species, because, although the bark of two varieties may contain similar amounts of quinine, still, as is often the case, one variety is more hardy and prolific than another, or may succeed better in different descriptions of soil and exposure. The *Pata* variety of red bark is an example in this way. I was almost going to say that it would pay a planter to make a trip to South America in order to study these and other characteristics of the *cinchona* in their native habitats.

Thus far I have made these remarks because I think that Ceylon, which now, of all the planting districts in the East, produces the largest quantity of *cinchona*, should also aspire to export bark of only the highest general quality. I shall now make only a few remarks on the indiarubbers. The Ceará and Pará trees will probably be found to succeed best at elevations of from 1,000 to 3,000 feet above the sea. The Ceará tree delights in a warm, dry, arid climate, and even in the most barren and sterile land in Ceylon it may be expected to thrive well.

The climatic conditions of the Pará tree are, however, different. I saw it growing most frequently in swampy districts bordering on the river Amazon which were daily covered by the tide to the depth of a foot or more. The *Castilloa*, which is one of the largest trees in tropical America, is adapted to the hot low-lying forest region bordering the coast of Ceylon. It will likewise thrive well in deep moist ravines and gullies, if not above 1,000 feet elevation. This tree together with the "red bean"—a very prolific variety of cocoa—are found to flourish best in the very hottest regions of the west coast of South America.—I am, sir, your obedient servant,

ROBERT CROSS.

ARECA CATECHU CULTIVATION IN CEYLON:

MR. BORRON'S EXPERIENCE.

Dear Sir,—As desired I have now great pleasure in giving you some information anent areca catechu cultivation :—

1. This tree is known to the Tamil as "pákku," and to the Sinhalese as "puwak." It is most extensively cultivated throughout the East, the nut being in general individual consumption as a masticatory, in conjunction with betel-leaf, lime and tobacco.

2. "It is considered to strengthen the gums, sweeten the breath and improve the tone of the digestive organs. The seed reduced to charcoal and powdered forms an excellent dentifrice. Dr. Shortt states that the powdered nut in doses of ten or fifteen grains every three or four hours is useful in checking diarrhœa arising from debility. The dry expanded petioles serve as excellent ready-made splints for fractures. The catechu yielded is of inferior quality, and has been used to supersede madder for dyeing a golden coffee-brown, 1 lb. being equal to 6 lb. of madder. The petioles can be written upon, and in India are used for making hats, umbrellas, fans, water-vessels, &c." The nuts ringed and strung with ivory on an iron rod make a very pretty but heavy walking-stick. I think there is no doubt that one object for chewing the nut is to allay the pangs of an empty stomach. It is a good vermifuge and used as such both in India and in England.

3. The most desirable elevation for cultivation should not exceed 2,500 feet above sea-level, but I have seen trees in bearing, though how old I know not, at about 3,500 feet.

4. The rainfall should not be low, and it ought to be as well distributed as possible. Last year's exceptional drought affected mature areca palms in the Matale district at an elevation of over 1,600 feet.

5. The lay of the land should be moderate. The formation of the leaves and stem collects the rain and washes away the soil from below the tree in steep land.

6. The soil should not be quartzy, and the better the soil the better the growth and crop.

7. Like all palms, the areca stands the wind well.

8. The presence of slab rock near the surface is very inimical, particularly in a dry climate. If it only gets the chance the areca is a deep feeder.

9. It is preferable to plant from a nursery with plants at least six months old than to venture to plant at stake, though I have seen this latter done with tolerable success.

10. The clearing ought to be kept carefully and systematically clean of all jungle stuff and flowering weeds, and a circle round each plant kept free from grass. So long as the heads are kept above cover, the plants can stand a good deal of neglect, but their growth and bearing will be seriously retarded.

11. The trees in my plantation of some forty acres are planted 10 by 10 in feet, and I would be sorry to risk any nearer distance. When natives plant closer it is usually only in a single or double line, and not over a broad space. The close native system of planting the coconut is generally understood to be a mistake, and certainly when I have tried it with the areca, even in single lines, I have found it so. It is quite possible that something closer than 10 by 10 might answer, but I will leave others to try. It is very long to have to wait seven or eight years to find out a mistake which can never afterwards be properly rectified. The close planting and subsequent cutting out is admirable as a theory, but who has the moral courage to ever carry it out properly, and it is wonderful how trees try to adapt themselves, as far as growth goes, to circumstances.

12. Few roads and drains are required in this cultivation.

13. The areca is a great surface-feeder, and so is injurious to other surface-feeding products, such as coffee, near it.

14. According to my experience, even with good soil, climate and cultivation, the areca does not come into bearing before its sixth year. Like cacao here and there a few precocious trees may blossom earlier, but on the other hand others may take very much longer.

15. The early blossoms frequently fail to mature their fruit.

16. Spring is the best cropping season upcountry, say January as the month for choice, but crop extends pretty well more or less throughout the year.

17. If a mature tree fails to give *at least* three hundred nuts per annum, then there is something wrong with the tree, the locality, or the cultivation.

18. The crop can be picked for local sale either three-quarters or fully ripe: the former gives the "kali pákku" preferred by coolies, the latter the "kotta puwak" preferred by the Sinhalese.

19. As my plantation is situated near a large town, I have never found the slightest difficulty in disposing of my produce gathered and delivered on the spot.

20. The price obtained has varied according to maturity, time of the year, and fresh or dried, from 37½ cents to 90 cents per thousand cash on delivery at estate store. Probably, with good management, the average might be taken at 60 cents per 1,000.

21. In Ceylon there are two kinds: the small-fruited upcountry areca preferred by coolies, and the large-fruited lowcountry kind preferred by the Sinhalese and, I suppose, also for exportation.

22. Your Colombo friends will best be able to quote prices of the prepared article for export, and its value in the London and Indian markets.

23. The only disease I have noticed is a canker that sometimes attacks the stem from the ground upwards in a long triangular form, but, except when it enables white-ants to gain admission, I have never seen much permanent harm done.

24. The great abiding and serious pest is the thief. The produce is of such universal use, so easily stolen, so difficult to protect, that, when grown on any large scale, the losses, even with much careful and expensive watching, are enormous, and no doubt this drawback checks extension.

25. The cost of planting and bringing an areca plantation into bearing, inclusive of cost of land and interest, should come to something like R200 per acre. It might be done for somewhat less, and, with indifferent management, it may take as much more as the greatest capitalist may be induced to give.

I trust you will now excuse my entering into any further detail. There are secrets in all trades, as I found when once applying to a Colombo merchant I was refused permission to visit his mills. As to Mr. Gladstone, so to the public, there are always three courses open :—1st, to be content with general facts

and figures ; 2nd to experiment at its own expend iture of time, trouble and money ; 3rd, to buy the technical detailed experience of others.

A. G. K. BORRON.

IMPROVED COFFEE CULTIVATION.

Kirimetia, Kadugannawa, 17th Feb. 1885.

Dear Sir,—The first outlay to carry out my plan of cultivating the coffee bush would be from £1 to £1 10s per acre according to lay of land and structure of soil and ever after one-third less than the present cost.

It would require a short treatise on horticulture to point out the how's and why's of the system: it cost me 180,000 minutes of time to mature it.—Yours faithfully, J. HAWKES.

PRODUCTS OF EUCALYPTUS LEAVES.

Colombo, 12th March 1885.

Dear Sir,—I asked you some little while ago if you had any information about the oil which is distilled from the leaves of the *eucalypti*. Not having heard anything in reply, I think the following may be of interest to you and your readers. It is a long extract sent me by my London correspondent taken from the extra *Pharmacopœia* 1884. In addition to the uses to which it is there said to be applicable, I may add that it is also a febrifuge, and the leaves are also employed as a healing application to wounds, as a tincture in intermittent fever, also in diphtheria. The oil is more than three times as strong as carbolic acid in preventing development of bacteria and not so poisonous. As regards the still, I should think any good copper one would do, such as are probably used in Ceylon for making essential oils.

Eucalypti folia, eucalyptus leaves.

Dose 5 grains or more in powder.

The dried leaves of the *Eucalyptus globulus*, or blue gum tree of Australia, have been employed medicinally in the treatment of ague and bronchitis, and are now much used in Italy for Roman and malarial fevers ; also, when coarsely powdered are employed for smoking in cigarettes, in cardiac, and aneurismal asthma. The narrow leaves, mostly scimitar-shaped, are more active medicinally than the broad leaves of herbaceous shoots. No alkaloidal principle has been discovered in them, or in the bark of the tree which also has been used in surgery. The medical properties are principally due to a volatile oil which is now largely imported.

Oleum eucalypti.

Dose 1 to 5 minims emulsified or mixed with olive oil.

Is principally distilled from the leaves of the *Eucalptus amygadalina* as well as *Eucalyptus globulus*, and probably other species. It is to this oil, and partially to the great avidity the tree has for water when growing, that the latter owes its anti-malarial influence. The oil is a powerful antiseptic and has an ozonizing influence on the atmosphere while it oxidises. It has a pale yellow colour, a penetrating camphoraceous odour, sp. gr. about 0·900 and boils between 338° and 392° F. It is not caustic, like carbolic acid, nor does it produce much irritation, although it is very destructive to low organic growths. It is soluble in oils, fats, paraffins, and alcohol, but only a trace dissolves in water. An emulsion may be made by putting equal quantities of powdered gum arabic and the oil into a dry bottle, and forty parts of water, more or less, and shaking well. This is useful as a urethral injection or lotion, and may be given internally in one to four drachm doses. The oil is useful mixed with an equal quantity of olive oil as a rubefacient for rheumatism. A large percentage of eucalyptus oil consists of *eucalyptol* which is also met with in commerce, and is that portion of the above oil which passes over between 338° and 352° F. It is obtained by treating the latter with caustic potash, then with chloride of calcium and subsequent distillation. Later researches have proved that it is a mixture of Terpeno and Cymene.

The foregoing is an extract from the extra *Pharmacopœia* published in 1884.—Yours faithfully, H.

P. S.—I learn from another correspondent that the oil is worth about 3s per gallon !

[We have frequently published similar information; and, if our correspondent wants to know all about the products of the eucalyptus, he ought to address Mr, J. Bosisto, M. P., Melbourne.—Ed.]

INDIGENOUS TEA SEED AND TEA.

Agrapatna, March 1885.

Dear Sir,—I am very anxious to have the opinion of some of my brother-planters as to the elevation at which indigenous tea will flush to pay in Ceylon.

My estate runs from 4,500 to 5,500. I wrote to a friend in Assam to send me the *very best seed* he could obtain for this elevation, and he sent me *pure* Assam seed from the *oldest* Assamese gardens.

I have planted about 25 maunds of this seed in nurseries, which is coming up well, but there appears to be doubts as to the pure Assam tea flushing to pay at this elevation.

I should be very much obliged if anyone of practical experience would give me information on the subject. I think I read in one of your recent issues that pure Assam tea flushed very well at a much higher elevation and in a much colder climate on the Indian hills. I am naturally very anxious about this seed as it has cost me a lot of money I cannot afford to lose, but, if there is no chance of the tea coming on to pay, I should not plant it out. The tea seed I received from Assam was as a rule very small and ran about 30,000 to 32,000 seeds to the maund.—Your obedient servant, HARD TIMES.

[Our own experience, as stated a short time ago, is that between 5,000 and 6,000 feet, seed got as best hybrid jât has flourshed, while "indigenous" has hung back.—Ed.]

MR. C. S. ARMSTRONG ON TEA "DRYING" AND "PLUCKING": VALUABLE PRACTICAL RESULTS:—THE NO. 1 SIROCCO A 1.

Rookwood, Deltota, 13th March 1885.

Dear Sir,—I beg to give you the results of two trials with my Sirocoos No. 1. I have stated the Sirocco No. 1 would work off 45 lb. made tea per hour, and the result of these trials proves this to be correct. My usual charge per tray is 9 lb. of roll. For the sake of experiment, I loaded the trays with all they would hold to allow of their being run into the Sirocco ; result, as will be seen, is in favor of the smaller charge 9 lb. per tray.

1st trial 100 lb. of roll or 12½ lb. per tray—Sirocco worked at 275°.

1	Tray fired off in	15″	100 lb. roll which gave 46 lb. tea.
2	,,	25″	
3	,,	28″	
4	,,	32″	
5	,,	35″	
6	,,	40″	
7	,,	50″	
8	,,	60″	

2nd trial 117 lb. of roll or 9 lb. per tray—Sirocco worked at 275°.

1	Tray fired off in	10″	117 lb. roll which gave 48 lb tea.
2	,,	15″	
3	,,	20″	
4	,,	24″	
5	,,	27″	
6	,,	32″	
7	,,	36″	
8	,,	40″	
9	,,	44″	
10	,,	48″	
11	,,	54″	
12	,,	58″	
13	,,	62″	

With regard to Plucking, the cost of this at the lower elevations and at the higher is about 3 cents in favor of the latter. At the lower elevations I find the cost to be from 9½ to 10½ cents ; this tallies with Mr. Rutherford's experience. In the one case, the flushes form more rapidly, and are not so large, the fields

having to be gone over at from 7 to 10 days. In the other, the fields are gone round in the hottest season at from 10 to 15 days, and in the colder weather at from 15 to 22 days; result in yield is about the same, always excepting "Mariawatte" with its perfect climate and lay.

My plucking at an elevation of from 5,000 to 5,500 feet cost as follows for the three seasons:—

Season—'81-82 5·57 cents per lb. } Average for 3 years
,, '82-83 6·86 ,, ,, } 7·08 cents per lb. tea.
,, '83-84 8·81 ,, ,,

The high cost of plucking last season is due to two causes: first, the unprecedented drought caused a stunted flush, during what ought to have been our best months; second, 90 acres of young tea was plucked for the first time, coolies only bringing in their 5 to 8 lb. of leaf from it. I think therefore my former estimate of 7 cents is about correct for high-grown teas, to which I then referred.

To revert to *driers*, there can be no question, I think, that those are to be preferred that do good work without motive power, to those requiring motive power, even should the cost of the former be more. Should the No. 3 Sirocco prove to be the improvement on the No. 1 it professes to be, it is in my opinion *the drier* of the day.

More anon.—Yours truly,

C. SPEARMAN ARMSTRONG.

CHEAP CINCHONA ALKALOIDS.

Dear Sir,—I am surprized that the statements respecting this, which you lately reprinted from the *Pioneer*, have met with so little notice. It was therein stated that "English manufacturers have been trying the Indian market with a *muriate of cinchonine* at R12 the lb."; also that "the Government now steps in with a preparation of cinchona febrifuge, which it can afford to sell at R6 per lb."

What I would like to know is, if either of these preparations have been yet introduced into Ceylon? and, if not, why not? Also, what is the nature of the febrifuge manufactured "by Government"? and how is it made to be saleable at one shilling per ounce?

CEYLON PLANTER.

[If our correspondent will refer to the back volumes of the *Tropical Agriculturist*, he will find full particulars of Mr. Gammie's mode of manufacturing cinchona alkaloids and of their cost. They are of course not so effective as quinine, and often produce nausea; but they are well worth trying. The great thing is to get a prophylactic into use among the millions of India and by-and-bye of China.—Ed.]

The "T. A."—A planter writes:—"What a valuable amount of good sound information is within the covers of the *T. A.* I have just heard from a leading member of the Botanic Society of Edinburgh (of which I am a life fellow) that he reads it with great interest. I am sure its usefulness is still more appreciated in planting colonies."

Bee-keeping in India.—Our American visitor of a few years ago, Mr. Frank Benton, as may be seen from an advertisement elsewhere, is still interested in Bee-keeping and the supply of the finest available "Queens" to would-be apiarians both in America and the Far East. Mr. Benton seems to have given up his post in the Michigan Agricultural College, to reside permanently in Munich, from which city he makes annual visits to South Austria and Cyprus. Mr. Benton sends us a copy of an interesting article on Bee-Culture in India which will find a place in the *Tropical Agriculturist*.

Mr. David Reid, late of Ceylon, in a recent lecture delivered in Scotland says:—The bright part of the future in Ceylon lies in tea. It has been found that the soil and climate of Ceylon are admirably suited for its growth. One estate planted on the very piece of ground on which the first coffee estate was planted by Mr. George Bird in 1824, and already alluded to, was planted in 1879, with tea, and has this year given a crop of 1,000 lb. of tea per acre, an amount never yet surpassed or obtained in the best tea gardens of India. Although the amount of tea sent to this country is as yet small in quantity, viz., under 3 million lb., yet this industry, having regard to its future, is even now the most important to the island, for it has now been proved beyond doubt that there are hundreds of thousands of acres of land capable of growing the finest tea in quantities over 400 lb. an acre. The knowledge of this is even now sustaining Ceylon credit and preventing a great deal of misery and ruin, of which there has of late been more than enough.

* * * * * * *

Although it will be long before tea equalling in value the biggest crop of coffee that Ceylon ever produced will be exported from the island, I anticipate that the day is not far distant when the general trade of the island will be as much stimulated by tea as it ever was by coffee. Tea requires so much manipulation that a far greater number of men per acre is required for carrying it on, and the extent of land available for tea is many fold greater than the land that was suitable for coffee. The number of coolies that must be brought from India will be doubled and trebled, wages will rise, more food must be grown or imported—in short, there will be good times again in Ceylon under the reign of King tea *vice* King coffee deposed. The pioneers of tea have one advantage over the pioneers of coffee in the excellent roads now to be found all through the island—roads that are the admiration of all visitors, and which, for smoothness of surface and neat appearance, put our Scotch roads to shame. —*Indian Planters' Gazette.*

The Proposed Separation of Northern from Southern Queensland.—A memorial was addressed to Lord Derby last January by certain investors of a large amount of capital in the north-eastern seaborde of Queensland, expressing sympathy with the present movement for the separation of the colony and giving some of the principal reasons which made such a separation desirable. The memorial states that Queensland has an area of 669,000 square miles, which it is proposed to divide by a line running West from Cape Palmerston on the east coast, in latitude 21° 30′, to the eastern boundary of South Australia separating the waters flowing north into the Burdekin and Gulf of Carpentaria from the waters flowing south. The tropical portion to the north of this dividing line has an area of 249,000 square miles (more than double the area of the United Kingdom), contains 50,000 inhabitants, and produces an annual revenue of £500,000. When Queensland was first constituted in 1859, her population was 25,000, and her revenue £178,589. The proposed new Colony has therefore double the population, and treble the income, of Queensland at the time of her separation from New South Wales. The reasons for separation are then given, being summed up at the end of the memorial as follows:—

On the grounds therefore

(1) Of the enormous territory and want of adequate supervision;

(2) Of the unjust dealing with loans and revenue;

(3) Of the great difference of policy as regards coloured labour; and

(4) Of the precedent afforded by the separation of Queensland from New South Wales in 1859. We sincerely trust that Her Majesty's Government will see their way to dividing tropical from temperate Queensland, equitably apportioning the public debt, and giving relief to the inhabitants of and those interested in Northern Queensland.

LONG BLACK CATERPILLARS have attacked the rape-seed and pea crops over the greater portions of the Purnea district, the former when it was nearly ripe for reaping, and the damage done in some places has been so complete that the royts have grazed down the crops with their cattle rather than pay the cost of gathering.—*Times of India.*

COPRA FROM CEYLON.—(Translated from the *Indische Mercuur* of the 21st Feb.).—The English (American ?) Consul at Ceylon, Mr. Morey, mentions the following respecting copra which is the kernel of the coconut :—"Formerly, copra used to be shipped exclusively to India, but during the past year it was chiefly exported to Europe, where it is converted into oil. Seeing that there are extensive mills for the oil manufacture in Ceylon, and that labour there is so much cheaper than in Europe, it would be of interest to learn the reason of its being thus exported. Perhaps it is to be found in the demand for a very pure oil. It is, however, well-known that coconut oil contains a constituent which in warm weather becomes quickly decomposed, and consequently the otherwise fresh tasted oil is rendered unfit for culinary purposes. As the copra shipped to Europe finds its way to the countries which are celebrated for the production of olive oil, it is very probable that chemistry there has discovered some process by means of which coconut oil may be so purified, that manufacturers are able to mix it with olive oil or even substitute it for olive oil, as has been done of late with oil from cotton-seed. In the expression of oil from copra in Europe, an incidental product is obtained in the shape of a sweet tasted oil-cake, which is excellent food for cattle. This cake was formerly only obtainable in Europe at high prices, and this may have caused the increasing demand for copra in Europe. Latterly, large quantities of it have been shipped for the Netherlands."

BADULLA (CEYLON) AS A TEA PRODUCING DISTRICT.—A tea planter writes to us from Badulla where he had gone for a short trip, as follows:—"A few showers have broken the long drought and freshened up everything here immensely, though they would like even more, I fancy. A great change is coming over this district, and in a few years, I think, some of the old patriarchs would hardly know it. I was through some tea planted only last November the other day, and was very much astonished and surprized at the good growth made. From what I have seen and heard I should think this is as good a district for tea as any in the island. The rainfall is more than sufficient, and though not so well distributed as it is in Awisawella, say, it appears to be quite as well apportioned as such places as Gampola, Nawalapitiya or Matale. The soil on all the places on which I have yet been appears to be very good—deep, rich, and free. There is an utter absence of that hard, gravelly stuff to be met with in parts of Ambegamuwa, though, as a rule, there appears to be a slight deficiency of iron in the soil. The rocks are mostly blue gneiss and there appears to be no end to them. All the estates round about Badulla seemed to me well suited for the successful cultivation of tea. Mausagalla and the Uva Coffee Company's places in particular. I did not see the Spring Valley tea planted where fine coffee stood a short time ago, but I hear it is doing excellently well. Looking at the question generally I should say the great difficulty to be contended against is the cost of transport. The railway must be made to Badulla as quickly as possible. Abundance of timber can be obtained not very far from here for tea boxes, but the present rate of transport on such requisities as tea lead and machinery would raise the cost of production very considerably, added to which *labor is dearer by 4c a cooly* than it is on our side of the country. A railway to Badulla would put an end to this. The high rate of all wages in Uva seems to be due to the high cost of living —rice and all rations—and for the matter of that European requisites being dearer than with us. A railway would bring down the cost of everything, wages included, and this would greatly help matters.—Local "Times."

CEYLON TEA AT HOME.—A gentleman engaged in the London Tea Trade writes on 20th February :—"Since I last wrote, there has not been anything of exceptional interest to report concerning our market, which remains firm for all kinds of good liquoring teas. Most of the late shipments of Ceylon teas appear to have suffered detriment from over-firing. This over-firing tends to put Ceylon teas on a level with the commoner kinds of Indian teas, and they consequently command near about the same price as Indian teas of this description are fetching. These have long been and are at present very cheap. I have just heard of the very large quantity of tea produced on the Mariawatte estate per acre : the proprietors are indeed to be congratulated on it, as most Indian tea estates consider 500 lb. per acre very good. The *Tropical Agriculturist* for January, I have read with much interest."

SUGAR DUTIES.—We gave in a recent issue the export duties levied on tea by the various British colonies. The following are the duties levied on sugar :—Mauritius, sugar, 4½d per cwt.; Jamaica, sugar, 5s 9d per hhd., 4½d per cwt.; St. Lucia, sugar, 4d per 100 lb., 4½d per cwt.; St. Vincent, molasses, 2s per puncheon of 90 gallons or more, 2½d per cwt.; St. Vincent, molasses, 1s 4d per puncheon (if less), 2½d per cwt. Grenada, molasses, 4s per puncheon of under 100 gallons, 4¾d per cwt.; Grenada, sugar, 4s per hhd. not exceeding 1,800 lb. 3d per cwt.; Grenada, sugar, 2s per tierce, not exceeding 1,000 lb. 2¼d per cwt.; St. Christophers, sugar 8s 4d per hhd. 6¼d per cwt.; St. Christophers, molasses, 1s 0½d per puncheon, 1¼d per cwt.; Nevis, sugar, 9s 6d per hhd., 7d per cwt.; Antigua, sugar, 5s per hhd., 3¾d per cwt.; Antigua, sugar, 3s 4d per tierce, 4d per cwt.; Antigua, sugar, 7½ per barrel, 3¾d per cwt.; Montserrat, molasses, 6d per puncheon, 3-5d per cwt.; Montserrat, sugar, 3s per hhd, 2¼d per cwt.; Dominica, molasses, 2s 6d per puncheon of 100 gallons, 3d per cwt.; Dominica, syrup, 4s per puncheon, 4¾d per cwt.; Dominica, sugar, 4s 6d per hhd., 3½d per. cwt.; Trinidad, molasses, 2s per puncheon, 2½d per cwt.; Trinidad, molasses, 8d per ½-puncheon, 1½d per cwt.; Trinidad, sugar, 6s per hhd., 4½d per cwt.; Trinidad, sugar, 3s per tierce (1,000 lb.), 3¾d per cwt.—*Home & Colonial Mail.*

A CUP OF TEA.—Most Englishmen who travel in France know how difficult it is to obtain a cup of tea. Even in Paris there are still very few hotels where the making of tea is understood. At one place they pour boiling water upon it, and then let it stew like a *pot-au-feu*; and in others they have not thoroughly mastered the fact that water must boil before it can be produced as a refreshing and invigorating cup of tea. And yet nearly all the resident physicians of Paris declare that a cup of tea would be a vast improvement upon the terrible decoction sold in Paris cafés as black coffee. Even when pure medical testimony is terrible against the national *demi-tasse*, some constitutions bear it bravely; but, as a rule, it is hostile to the liver and destructive to the nerves. *Café au lait*, constantly taken, is not much better, and just as the present generation of Frenchmen have become beer drinkers in a far greater portion than we have become wine drinkers, so it may be safely predicted that the taste of an honest cup of tea will become a feature almost Parisian of the future. The real origin of the hesitation of the French, in the matter of tea drinking, is the slipshod state of the tea-trade in France. Of provincial towns we need not speak, for there the buying and selling of tea is as unfrequent as that of any other drug at a chemist's shop in England. But even in Paris there are no experienced tasters, and the consequence is that the trades are imposed upon by high sounding names. When analysed, these wretched mixtures are found to be full of colour, but utterly worthless, and everything goes to prove that the elements of the tea trade are not understood by the French grower. He never knows how to taste or how to blend. The result is that his customers suffer, and that the French people slassify tea with their national tisanes, instead of realizing that it a delicious stimulant, with many of the qualities of coffee and alcohol, and very few of their disadvantages.—*Home & Colonial Mail.*

Pinus Sinensis.—This wood, so largely used by the Chinese for Tea-boxes, is, we learn, growing well in the forest nurseries formed in the east of Cape Colony. There seems no reason why it should not succeed in the Himalayas. We commend this matter to the attention of the Agri-Horticultural Society. —*Indian Tea Gazette.* [And why not on the Ceylon hills ?—Ed.]

A Cure for Thirst.—An old Indian writes to the *Standard* :—I see that your special correspondent states that our soldiers in the Soudan suffer greatly from the dry air of the desert ; that their faces get parched, and that, they are tempted to waste their precious supply of water. I have lived for many years in India, and perhaps my experience will be of a little service when I say that a little olive or other vegetable oil rubbed over the lips and face will prevent the parched feeling complained of, and that a small piece of lime or lemon in the mouth will check thirst. It ought not to be a difficult matter to provide a lemon or two for each soldier leaving Suakim for Berber.—*Pioneer*

Cotton.—There will be a splendid crop of cotton in Egypt this year estimated at three millions and three-quarters of cantars, the largest quantity ever-grown, and at the same time the quality is above the average. In a few years, when Colonel Scott Moncrieff's irrigation work and plans are more advanced, and when lands, now waste, are luxurious with cotton, wheat or sugar, and when English rule has a fair chance, Egypt will, says an Alexandria correspondent, again become the land of Goshen.—*Madras Mail.*

The North Borneo Company has recently been lengthening its cords and strengthening its stakes in the shape of taking over fresh tracts of country. While wishing well to the enterprising gentlemen who have undertaken to farm Northern Borneo, we must confess that we should have heard with more satisfaction that they had been engaged in strengthening their administrative system so as to enable our Government to rebut conclusively all complaints brought against the British administration of those regions by Powers whose subjects consider themselves inadequately protected. Unless we are considerably misinformed, there is a storm brewing in that quarter which bodes no good either for England or the chartered company with which Mr. Dent and Sir Rutherford Alcock are so closely associated.—*Pall Mall Gazette*, Feb 27th.

Tanned Snakes and Frog Skins.—Even the delicate skin of a frog can be tanned. An opera glass covered with the handsomely marked skin of a garter or a small water snake will become fashionable. Card cases, small books and little bedroom clocks are some of the articles in the manufacture of which they are used. The surface of the skin is thickly glazed and in such things it takes a long time before the scales begin to stand up. The upper portion of slippers and shoes and even dressing-cases are made from the larger snakes. Nearly all of them come from Africa, but a good many are also obtained from Brazil and other parts of South America. It is a singular fact that the skins have to be taken to France to be tanned. —*Detroit Free Press.*

Cinchonas in Java are thus noticed in the letter of the *Singapore Free Press* from the Dutch Colony: — I am glad to see at last one Government resolution of the 28th Dec. last, whereby it is decided that, for the future, slips and seeds of the Government Kina plantations of the C. Ledgeriana, Succirubra and Officinalis, which they do not require themselves, will be sold at public auction without limited prices. It will hardly be believed or credited by those who do not see enough of our short sighted colonial policy, that till now, whenever these superfluous slips and seeds were offered at auction, and private planters could not afford to pay the high prices fixed by Government, the slips and seeds were ordered to be carefully destroyed.

Croton Oil Seeds for Haputale.—Golconda last sales of croton oil seeds (about 5 cwt.) realized 65s per cwt. and quoted "fine fresh."—*Cor.*

New Galway, 20th March.—Very busy in a general way with tea, and our coffee crop is only now coming in. I have not much to tell that's new. Coffee, tea and cinchona are now looking well, except patches of the former that have had a second dose of *H. V.* A large area of this district is likely to be put into tea during the coming year. I should think wheat and barley would grow in Uva, and Government should give a few enterprizing natives some seed, or, better still, have say two acres planted on Government account to show it will grow.

No Sugar in Theirs.—Fancy attempting nowadays to live a single day without sugar, no tea, no coffee, no jam, no pudding, no cake, no sweets, no hot toddy before one goes to bed ; the bare idea of it is too terrible. And yet this was really the abject condition of all the civilized world up to the middle of the middle ages. Horace's punch was sugarless and lemonless ; the gentle Virgil never tasted the congenial cup of afternoon tea ; and Socrates went from his cradle to his grave without ever knowing the flavor of peppermint bull's eyes.—*Detroit Free Press.*

Encouraging News of Tea Grown at High Altitudes in Ceylon.—A correspondent writes :—"My totam is at an elevation of from 5,000 to 6.000. The tea in bearing—only a small acreage running from about 5,000 to 5,500—five years old on October last pruned last December : average yield to date of made tea is 512 lb. per acre. Broken Pekoe reported on in London as very fine, worth 2s 4d to 2s 6d per lb. and could take any quantity at that figure : jât fine Assam hybrid almost indigenous and mixed with pure indigenous."

The Tea Duty : Bogawantalawa, 12th March.—We have been enjoying most seasonable weather for the last two months, and, although blossoms are late, there is every prospect of a good coming crop. The rapid growth of tea is surprising everyone, and it is sincerely hoped that the threatened increase of duty (3d per lb.) will not be enforced. At 400 lb. per acre, it means R50 per acre off the proceeds, and that means all the profit ! We ought to memorialize Government at once. It will all come on the poor producers, say what people like.

The Proposed War Tax on the "Cup that Cheers."—Says the *Madras Mail* :—In 1864 the United Kingdom received 7¼ millions of lb. of tea from China, and ¼ million of lb. from India. In 1874 the China tea amounted to 10 millions, and the Indian tea to 2 millions of lb., and in 1884 the China tea amounted to 9¼ millions of lbs., and the Indian tea to 5¾ millions. So that already the consumption of Indian tea in the United Kingdom is in the proportion of nearly 2 to 3. So if the duty is increased as proposed, two fifths of the yield therefrom will be obtained from Indian and three-fifths from China tea. This is hard upon India after the sacrifice of her import duties to please England.

Brazil Rubber Tree.—Consequent on the decreasing supply of raw rubber in the past few years, a law has been passed in Brazil, prohibiting the tapping of rubber trees about 2½ metres from the ground, the tapping of of young trees, or those less than twenty-five years old, and the injury or destruction of young trees. The fine is fixed at $1,000 each infraction, and as an encouragement to planters a premium of $1,000 is offered for each thousand trees planted and cultivated, at two years of age, besides other favours to cultivators. To guard against foreign competition, an export duty of $5,000 is levied on every rubber plant, and $100 on every kilogramme of rubber seed exported.—*Printing Trades Journal.*

PROGRESS IN TEA CULTURE IN CEYLON.

There were many observers who ventured the remark that the large Tea Factory for the Kadawella group of estates in Ambagamuwa was surely being constructed for the next generation with its three floors 130 feet long by 30 feet wide. That all this space could not be wanted for the ordinary requirements of the property seemed a common opinion. But these critics will, perhaps, be surprised now to learn that the imperative need of more "withering" room has led to the commencement of an extension of this Factory by another building which will be 110 feet long by 30 feet wide and with two floors. It is a question even whether this will suffice when the whole of the 800 acres of tea on the Kadawella group are in full bearing. At present only about half the acreage has reached this stage, though the Factory buys the leaf of some twenty other gardens in the neighbourhood or within reach.

As showing the progress made in economical working, we may mention, that, if the estimate of crop for the current season be realized—and there is at present no reason to doubt it will—the cost of the tea from the oldest estate of the Kadawella group is not likely to average more than 28½ cents per lb. f. o. b., against the 32 to 35 cents which is the generally accepted rate. Not only so, but it is reported that of tea from Dunedin, for the current season, the cost is not likely to exceed 26 cents per lb. In fact, it is quite evident that with all the facilities for cultivation, manufacture and transport which Ceylon offers, there is no reason to doubt that many of our tea planters can supply their produce equal to the average of Indian tea at not more than 25 cents f. o. b. at Colombo when the tea is in full bearing and everything in proper working order. This rate of four annas is, we need scarcely say, far below anything that has yet been done in India, and would seem to show that Ceylon is destined to eclipse her big brother altogether.

We commend these figures to the notice of Colonel Money. His words of warning as to continuous and over-plucking will, we hope, receive due attention; but it is impossible for any one to judge of the tea industry, the style of cultivation and cropping in Ceylon, without a personal visit. Colonel Money admits that our climate is very different from that prevailing in the North Indian Tea Districts, and he must know that experienced Indian tea-planters who have inspected the work here, have had their criticism disarmed and have gone away, most favorably impressed with the prospects of our industry. To give one instance, a visitor to Abbotsford—an Assam proprietor and planter—when he heard of the crop taken from trees between two and three years planted out—thought the plucking too heavy and unwise with reference to the growth and permanency of the trees. 'We prefer,' he said, 'to allow our trees develop good large stems before plucking so heavily.' But when taken to the field so cropped (close on 6,000 feet above sea-level), he declared that nowhere in Assam had he seen more vigorous bushes or thicker stems on trees of their age; and we who saw the field for the first time a few days ago have, as yet, nowhere else seen finer two to three years old tea bushes. No doubt there are fields as good in growth, if not better, in the Awisawella-Yatiyantota-Dolosbage districts, for, a note from our 'Senior' reports that on Awisawella estate (Mr. Karslake's), he has just seen tea and cardamoms equal, he supposes, to any in the world. Colonel Money's chief practical suggestion (page 785) is that the Ceylon planters should endeavour, malgre climate and growth, to give their tea-gardens a complete rest for three or four months in the year after the fashion (enforced by nature) in Northern India. Our morning contemporary in taking over from our columns this letter has the following apropos remarks on this point:—

> The high yield per acre obtained here is not because of the *continuous* plucking indulged in by planters, but is the result of the rapid growth of flush in the height of the season. Quite 75 per cent. of the yield of an estate is obtained from March to September, the amount plucked from October to March being insignificant. Let us take the yield of Mariawatte which has been given in these columns, month by month:—
>
> | | lb. | | lb. |
> |---|---|---|---|
> | January.... ... | 4,298 | July ... | 14,830 |
> | February... ... | 4,124 | August ... | 13,236 |
> | March ... ... | 5,138 | September ... | 11,132 |
> | April ... ... | 14,607 | October ... | 8,102 |
> | May ... ... | 16,544 | November ... | 2,611 |
> | June ... ... | 13,188 | December ... | 1,393 |
>
> From April to September—only six months of the year—the yield of this estate last year was 83,537 lb. equal to 835 lb. an acre, whereas the other six months gave no more than 25,666 lb. Now, what would Colonel Money advise should be dooe in such a case in order to give the trees their much-needed yearly rest? Pruning was commenced in September, we believe, and was almost completed by December. In that month the few lb. plucked—some 1,393 lb.—were taken, not with the object of grabbing everything in the way of a flush put forth by the trees, but in order to prevent the young flush running quite away. The trees pruned in September had doubtless long shoots early in December, which, if not lightly plucked, would grow quite unmanagable and unpluckable in a very short time, and the planter is *forced* to check the growth in this way in order to shape his bushes. It is not possible to abstain from all plucking during so long a period as three or four months, seemingly advocated by Col. Money, who could not recommend such a course to Ceylon planters were he acquainted with the peculiarities of our climate and the conditions surrounding us.
>
> But the time of comparative rest for the trees differs very much in different districts in Ceylon. It partly depends on the time of pruning, but still more on the variation of climate in accordance with altitude. Thus the very months given as the slackest on Mariawatte under 1,500 feet in the neighbourhood of Gampola (and which hold good for most low estates), are among the busiest with flush in the higher districts. Take Abbotsford (5,000 to 6,000 feet) for instance, and the monthly return for 1884 was as follows:—
>
> | | lb. | | lb. |
> |---|---|---|---|
> | January ... | 3,938 | July ... | 803 |
> | February ... | 7,582 | August ... | 1,228 |
> | March ... | 6,568 | September ... | 2,343 |
> | April ... | 5,984 | October ... | 3,711 |
> | May ... | 3,719 | November ... | 7,799 |
> | June ... | 1,290 | December ... | 10,758 |
>
> 1885: Jan. and Feb. and March to end of 11th week 22,112
>
> [So that the first quarter of the year is likely to be the busiest, at any rate the months December-March.]
>
> [These figures are compiled from the weekly returns and are therefore not quite correct according to the calendar month division, but they are near enough for our present purpose and the total is of course right.]
>
> As to pruning, we know of estates where a pruning once in eighteen months has answered admirably, the tea bushes cropping and looking exceedingly well, and very many planters are coming round to the opinion that in good soil, or when manured, tea gardens in Ceylon need only to be pruned twice in three years. To get a proper idea of the slack time on Ceylon tea gardens as a whole, we need only refer to the table of monthly exports from Colombo, for our tea planters (unlike many coffee planters in the early days) are not obliged to keep their produce one unnecessary day in store before despatching it for shipment. The following return made up from the Chamber of Commerce table will show Colonel Money that, if not an entire stoppage of our tea plucking and exports, there is at

least, a marked difference between our busy and slack months :—

PLANTING IN THE LOWCOUNTRY OF CEYLON.

GENERAL REPORT: THE DROUGHT—TEA—RUBBER—PEPPER VINES.

Henaratgoda, 20th March 1885.

The drought broke up on the 12th instant, and for six days more or less rain fell daily. During the long dry weather the tea did not altogether cease to grow, but the progress was very slow, and every leaf developed, hardened before another bud opened and though the rain has fallen daily for a week past there is no vigorous start yet. The drought lasted seventy-six days, broken only by four or five light showers with long intervals, and it has tried the tea very severely. The vacancies in last year's planting are in some places very numerous and many of the plants pruned in January look bare and stunted; there is however now no doubt that tea can stand a good deal of drought without serious or permanent injury where the plants have got a firm hold of the ground.

The new field of 16 acres is a very fit lay, but the soil is not all that I could desire. I got the last section burned off three days before the rain came; the last felled portion would have been better for a few days more sun, but I dared not to wait, and the clearing up has consequently been a stiffer job than was desirable. The lining is well advanced and holing begins on the 23rd. I have the belts of bamboo in the old field nearly all down but they will want constant attention to keep them down so long as a bud remains on the stumps. In another week the tea-house will be ready for the roof. I will begin filling in the failures in the tea fields as soon as the little monsoon begins, but I cannot venture just yet The nursery of Assam indigenous will not be ready for a month, but the older nurseries are now ready for operations.

The Rubber harvest is over for this spell, and something has been learned, but not enough to decide the question of "Will it pay?" Individual trees have in the course of two months yielded over one pound, but others that have been operated on have not given an ounce and some none at all. The result from twenty-five trees is 14 lb. perfectly clean, and its value in the European market must decide whether it will be worth while dealing further with it One-half of the trees may be destroyed with advantage; the causes: stunted growth, scanty yield, and low quality. The most productive trees are mostly those that have branched low and are not crowded: I should say 20×20 feet apart or 108 to the acre would be about the thing. On this occasion the single boy I employed in collecting has averaged somewhat under half a pound daily, but this first attempt has not been got into a regular system before the passing away of the proper season.

I have partially succeeded in getting Pepper Vines to run on the rocks, but unfortunately they do not yield fruit in that situation however luxuriant the growth, while those attached to living trees give very scurvy crops: the only real success with pepper is on dead stumps.

The imbul trees are getting on and cropping where it has been possible to protect them from cattle.

Sentence of extermination has been pronounced against the Liberian coffee.

THE POSITION OF INDIA TEA

Was thus noticed by Mr. D. Cruickshank at the annual meeting of the Calcutta Tea Association :—

From the brokers' sale lists I find that the average price realized for the portion of the past season's crop sold in Calcutta is 8as. 9 pie per lb., and we may take this to represent also the value of the teas sent direct from the gardens to London, where the range of values will not be found, I think, on the whole, to differ materially from that current here. Taking then the value of the crop of 1884 at 8as. 9 pie per lb., and the average yield at 3¼ maunds, in order to obtain a return of say 10 per cent. on a capital of R500 per acre, there should be a margin of fully 3as. per lb. between the cost of production and the price realized for the teas. This would necessitate the teas being laid down in Calcutta at less than has. per lb., and we all know that very few gardens have hitherto done this. The average cost of Assam, Cachar, and Sylhet teas in Calcutta including charges for selling, is probably about 8as. per lb. for 1884. In some concerns the cost of production may have been less, but in a great many cases last season I fear it was more.

I have troubled you with these figures as they help to show the critical position in which the tea industry at present stands and the absolute necessity for a reduction of expenditiure in the absence of any prospect of a material rise in prices, which the increasing production that may be expected from the large extensions carried out of late years both in India and Ceylon render very improbable.

Without taking an alarmist view of the situation it is evident that gardens cannot go on for any length of time producing tea at a cost greater than the price obtained for it, and unless a remedy can be applied, many estates will eventually have to be closed with disastrous consequences to the proprietors and those employed by them. Attention has for some time past been directed to this subject and efforts made to reduce expenditure, but more remains to be done. Managers have much in their power in connection with this matter. The bulk of the outlay for working a garden is for labour and stores, and upon the careful use or the abuse of these by a manager may depend the question of profit or no profit. Managers must recognize this and act accordingly.

We find one manager making his tea at a local cost of 4as. per lb. while his neighbour, working under similar conditions, but with less attention to economy and to the judicious application of his labour to the work requiring to be done, runs up his expenditure to 5as. and 6as. per lb. The cost of importing labour has, by the extension of the system of recruiting by garden sirdars, been considerably reduced during recent years. Prices of manufacuring and other stores are also lower and considerable reductions have been made in the rates of freight to and from Assam. Machinery is still a heavy item of expense more especially since the introduction of tea dryers some of these machines with the frequent renewals they require, alterations and improvements, entailing a heavy outly on gardens in addition to their original cost. The principal expense on garden is for labour, and attention must be directed to the possibility of effecting a large reduction under this head. This may be done by a more economical use of the labor available and by getting better work from the coolies so that fewer hands will be required.

There is one other matter to which desire to allude briefly, and that is the question of the alleged falling off in the quality of Indian teas. In a review of the Indian tea trade for the year 1884, published by a firm of brokers in London, I find the following remarks :—

"The trade generally are commenting freely and with regret at the gradual but market deterioration year by year in the quality of Indian teas, and it is commonly asserted that Indians from 1s downwards cannot now compare as they did in value with China of the same price. This assertion we consider to be only too true, and a most unpleasant fact for the contemplation of those interested, and we believe it points to the fact that we have not yet witnessed the lowest prices in such descriptions of teas." The assertion here made that Indian teas show a marked deterioration in quality is not generally supported by the opinions of those here who are in the best position to judge, and I do not find any such sweeping condemnation expressed by any other London firms. I think it will be admitted that as a rule the care and at-

tention given to manufacture has not diminished, and the appliances for the work have improved. It is true that some individual marks have from time to time shown a falling off in quality and it is thought that in some cases teas have been injured by the use of drying machines, either from defects in the machines themselves or from ignorance or carelessness in the working of them. The defects observable in the produce of gardens which have made no alteration in their system of manufacture except in the introduction of drying machines, would certainly point to the latter as the cause of the falling off in quality, but experiments which can easily be carried out should show conclusively whether this supposition is correct or not. These dryers all require, more or less care and special knowledge in working, and I trust it may prove that any injury shown to have been caused by them has arsien from ignorance as to the proper way of using them, and not from defects in the machines. It would cause serious inconvenience to many gardens on which the supply of timber is limited, if they had to revert to the use of charcoal for drying purposes. One noticeable feature in connection with the prices of Indian teas is the smaller difference which now exists in the relative values of the higher and lower grades. We find good Pekoes now selling at very little over the prices obtained for Souchongs. This would indicate that the trade at home are not prepared to pay up for fine teas, and as planters are obliged to study the requirements of the market, the result must be, unless a change takes place, that coarse plucking will be resorted to and the crop will show a larger proportion of the lower grades. This result would be a matter of great regret to all who are anxious to see fully maintained the superiority which Indian teas have attained. If buyers want fine quality, however, they must pay for it, and I trust when the great depression in trade generally which at present prevails has passed away, that we shall again obtain for our Pekoes and other fine teas the relatively higher prices which they have heretofore realized. —*Indian Planters' Gazette.*

MR. COMMISSIONER ELLIOTT IN ASSAM:

TRANSPORT IMPROVEMENTS FOR THE TEA PLANTERS

The temporary severance of Mr. Elliott's connection with Assam seems a proper occasion for some brief review of the four years during which he has been the ruling spirit of that Province. His administration was expected to be one of progress, and it does in fact bear that character when examined in detail. To begin with, Assam has been made more accessible. It may not be generally known that the frontier station of Assam is the little town of Dhubri on the Brahmaputra, and that Dhubri can be reached by a journey of 21 hours by rail from Calcutta, supplemented by four hours' steaming up the river. Proceeding eastwards through the centre of the province, the next headquarters of a district is Gauhati, 150 miles higher up the Brahmaputra, then Tezpur, 110 miles further, and so on until one reaches the easternmost station, Dibrugarh, 450 miles from Dhubri. All this journeying is performed by water, for stage vehicles are unknown upon the trunk road, which runs parallel with the river, and the road itself, being unmetalled, is not a good highway for traffic during the rainy season. Until quite recently, the traveller bound for the upper districts of Assam was obliged to await at Dhubri the arrival of one of the weekly steamers, which took him in four days to Gauhati, and continued its progress upward at the same leisurely rate, and even this rate could not be reckoned on in the dry season, when steamers were often stranded for days together. Now, however swift passenger steamers ply daily on the river, covering the distance between Dhubri and Dibrugarh in four days, and the return journey in three, this immense convenience being the result of negotiations between the local Administration and a Calcutta firm. At the same time it is felt to be merely a preparatory step to still more rapid means of communication. The project of a railway for Assam has found a strenuous supporter in Mr. Elliott, and the Province is fortunate in having an advocate of so much weight with the Government of India. While the inter-provincial line between Dacca and Silchar is still in the stage of survey, and the last link of the Calcutta and Dhubri line is awaiting completion, Assam has been furnished with three local railways of its own. The Jorhat Railway (originally designed by Sir Steuart Bayley) enables the best tea-growing tract in the Province to deliver its produce on the banks of the river; the line from Dibrugarh to the Makum coalfield taps an inexhaustible supply of first-class coal, and opens up an incalculable store of natural wealth for the Province; and the tramway and railway line to connect Sylhet with the Khasi hills will give an adequate outlet for the trade which has hitherto been compelled to accommodate itself to the very unsatisfactory means of carriage afforded by the backs of coolies. The same energy has marked other branches also of public works. Assam is greatly better off for roads and bridges than it was four years ago. Two of the largest stations are being supplied with pure water laid on in the streets, a boon which wealthy municipalities in older Provinces might envy. Shillong itself has grown with the growing age, and new structures of stone, not wholly devoid of architectural pretensions, afford better accommodation to the Government offices and the administrative archives of the Province.—*Pioneer.*

THE PROPOSED TRAVANCORE RAILWAY AND TEA PLANTING.

"Planter" writes to us from Ceylon:—

I have been much interested in the correspondence appearing from time to time in your columns anent the proposed Travancore Railway, and in giving an opinion on the matter I may confess, to begin with, that I am, perhaps, unwittingly prejudiced in favour of the Northern route by the fact of my interests lying in that neighbourhood. It seems to me that the strongest point urged against the Northern by the advocates of the Southern line, is that the former would pass through a large extent of forest and waste land that would give little or no traffic to the railway when made. Now, I think I know that part of the country pretty well, and I say that for soil and climate it is not surpassed by any district in Ceylon as regards its capability for tea, and the forests ought to be a mine of wealth in themselves if they had the facilities for transit of sawn timber and firewood that a Railway through them would give. So far as we can see at present, the rush that is setting for tea in Ceylon will be quite unprecedented in the memory of the present generation of planters; and, if the Travancore railway should be made by the Northern route, a considerable share of the money that will be invested in that enterprize would, undoubtedly, be diverted to that country, if land along the line could be got on reasonable terms. From the point where the line would touch the hills on the Tinnevelly side, to where it would leave them on the Quilon side, and for miles on either side of the railway, the land would be rapidly taken up for this product, and, with the advantages planters would have in cheap labour and transport, and abundance of firewood and timber for boxes, I believe that Travancore would produce tea at a cheaper rate than any other district in India or Ceylon.

It is calculated here that every acre of tea in full bearing gives one ton of traffic to the railway in the course of the year, and it would, therefore, lie pretty much with His Highness the Maharajah himself whether or not the hill portion should be the

mainstay of the whole line. Now, if the Southern route were adopted, no great increase on the present traffic could be looked for, passing, as it does, through a country where the native wants are few, and where they produce for themselves the bulk of what they require; and this is borne out by the experience of the Ceylon railways, where the line passes through about 50 miles of similar country to Travancore before it reaches the hills, and where the traffic is almost entirely composed of estate produce down, and food-supplies for labourers, and manures up.

To make the scheme complete, the Quilon harbour should also be taken in hand; and if it were, who could doubt that the line would pay handsomely, and that a great portion of the export and import trade of Southern India would pass over it? The Quilon cotton mills and the proposed paper mills already shown in which direction the current of business inclines, in spite of present difficulties, and they would be multiplied many times if shipping and railway facilities were supplied them.

His Highness the Maharajah is too prudent to show any decided personal perference for either route; but with his acknowledged ability as a ruler and his intelligent grasp of the requirements of his country and people, and seconded as he is by a Prime Minister whose admirable fitness for his position is well known, I look forward with confidence to the time when a Travancore Railway, *via* Camp Gorge, to Quilon, will be paying its 10 or 12 per cent. on cost of making a similar one here has already done.—*Madras Times.*

NOTES FROM UVA, CEYLON.

Haputale, 20th March 1885.

There is not much to report from this district since date of my last, beyond that the weather has been very dry indeed and almost quite unprecedented in my experience of weather at this time of year. Scarcely a third of the rainfall which was experienced last year has fallen to date this year, the register kept on Happootella estate has been kindly furnished to me by Mr. Andrews, and is as follows:—

	1885.		1884.
January	1·42 inch	against	2·07 inches.
February	0·72 „	„	4·49 „
March to 15th	0·39 „	„	5·06 „
	Total...2·53 inches	against	11·62 inches.

Fortunately this unusual drought was dispelled by a few heavy showers of rain during the end of last week, falling more or less all over the district, and clouds are still hanging about from which we may get more rain. Spring crop tis holding back and will ripen up with a rush next month.

Carts for conveyance of what little crop is already gathered are plentiful at present and drivers competing with one another at low rates of hire, asking only fifty cents per bushel parchment from the top of the Pass to Colombo and doing the journey all the way by road in unusually quick time. I loaded some cinchona bark on the evening of the 5th instant at Haputale Pass in a cart, which was delivered in Colombo on the 12th: the waybill was made out "to be conveyed all the way by road,"—112 miles in six days for a cart is unusually quick time. I fancy Appuhami thinks it best to make hay while the sun shines and before the railway looming in the distance drives him off this road too and when he will find his vocation of coffee-stealing gone. The Cart Registration scheme or Carriers Ordinance, as worked by the police, must be doing good work and keeping cartmen up to the time in delivery, when any delay occurs between station and station the bobbies are nowadays so zealous and anxious to get "bucksheesh" from the "durais" when they detect anything wrong (not to say anything of how innocently bobby can fleece Appuhami) that the poor cartman have not got it all their own way. The streams along the Ratnapura road and the Kaluganga will once more run smoothly along, as little water will be required to increase the weight and improve the colour of Uva coffee, once we get the railway at the top of the Haputale Pass.

Recently I had an opportunity of tasting some tea manufactured on Gonamotava estate by Mr. J. Orchard and found it very good. We now have *three* estates in this district: St. Catharine, Gonamotava and Kalupahani at respectively high (5,000 ft.), medium (4,000 ft.), and low (2,000 ft.) elevation—three estates that can turn out manufactured tea on a very small scale. Some ladies in the district have pronounced all three samples excellent, and who will be so bold as to deny that ladies are not the best tea-tasters in the world? A hint to bachelor tea planters—get married.

ALCOHOL IN TODDY.

TO THE EDITOR OF THE "BOMBAY GAZETTE."

Sir,—With reference to certain correspondence on the Abkari system which has lately appeared in your columns, the following facts may prove of interest, as showing that toddy, even when freshly collected, is an alcoholic liquid, and not a non-alcoholic beverage like tea or coffee, as asserted by one of your correspondents.

Between March 1883, and May 1884, I examined a large number of samples of freshly-drawn toddy. I found that, when toddy is collected in the usual way, in pots which have previously been used for he same purpose, it is invariably, on removal from the tree, in an active state of fermentation, and contains more or less alcohol. Of eighteen samples of toddy collected in March 1883, I found the average strength at 9 o'clock on the morning of collection, or three hours after the removal of the pots from the trees, to be equal to 5·6 per cent of prots spirit. The same samples at 2 p.m. on the same day, or eight hours after collection averaged in strength 7·5 per cent of proof spirit. About twenty-four hours after collection the average amount of alcohol contianed in the same sample equalled 10·2 per cent of proof spirit. As will be seen from the figures below, this means (1) that the average strength of the samples three hours after removal of the pots from the trees was more than twice as great as that of London small beer, and over two-thirds of that average London porter; (2) that eight hours after removal from the tree the average strength of the samples was about the same as that of average London porter; and (3) that about twenty-four hours after removal from the tree the average strength of the samples was slightly less than that ofaverage London ale:—

	Quantity of proof spirit per cent.
Toddy 3 hours after collection ...	... 5·6
Do. 8 hours do. ...	... 7·5
Do. about 24 hours do. ...	... 10·2
London small beer, average (Brande) ...	... 2·3
Do. porter do. do. ...	... 7·6
Do. ale do. do. ...	... 11·2

Very similar results were obtained from experiments on samples of toddy collected month by month during the year ending May 1884. J. B. Lyons, F.C.S., F.I.C.

Grant Medical College, Feb. 23rd.

Millipedes in Soil (H.J.).—When we find land so infested with the pests of which you enclose samples—a species of Julus—we have always a suspicion that it needs draining. If this is so in your case, and you can determine the point by a few trial holes in winter, you should drain it effectually. When water settles in excavations 2 feet deep draining is needed. If the ground is not naturally wet then we should give it a very heavy liming. Unslaked lime should be placed in convenient heaps at the rate of 100 bushels per acre at least, the heaps to be covered with soil dug from around them. In the course of a short time the lime will swell and burst through the soil, the moisture causing it to "fall," when it should be spread and forked in as quickly as possible. The best plan is probably to ridge up the land before the winter, level it down in spring, and use the lime then when the soil works freely.—*Journal of Horticulture.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, February 26th, 1885.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£6 10s a £8
Yellow	Do. drossy & dark ditto	£5 10s a £6 5s

TIMBERS IN USE IN THE STRAITS SETTLEMENTS.

Mr. Howard Newton, A. M. I. C. E., Assistant Municipal Engineer, Singapore, has published a useful series of "Notes and Experiments on the Different Kinds of Timber in Ordinary Use in the Straits Settlements," inscribed to Governor Weld. The brochure is well and clearly printed at the "Singapore and Straits Printing Office." In some prefatory remarks, Mr. Newton states what is patent to any person visiting Singapore, that, what with trees felled for timber purposes and jungles cleared and exhausted by the Chinese gambier and pepper planters, it must be merely a question of time how long supplies will last, unless planting and conservation are resorted to. These remarks will soon apply to the native states as well as to the British settlements. We quote as follows :—

The Chinese are largely engaged in the trade of hand sawing in the jungle and in felling and hewing squares almost everywhere within easy reach of water carriage, and this kind of work has been carried on continuously since the establishment of Singapore. The Johore Steam Sawmills, the property of H. H. the Maharajah of Johore which have been working for about 20 years have consumed vast quantities of timber, while the smaller sawmills more recently erected in Singapore must have helped to make the forests thinner. It cannot therefore be urged too strongly that, unless planting and supervision of forests is inaugurated in these parts as in India, the better kinds of timber will at no very distant date be unobtainable.

The chief source of supply in Singapore is from the territory of Johore and the neighbouring islands, but certain kinds of timber are also imported into Singapore from Pahang, Sumatra and Borneo.

The vast forests of the interior of Johore are still intact, but owing to the want of roads perfectly unavailable. All the most useful kinds of timber, such as those experimented upon, have disappeared from the banks of the rivers, and it is only by penetrating farther into the jungle or going greater distances along the coast that they can be obtained. That enlightened native Prince the Maharajah of Johore is now considering a proposal to make a railway into the interior of his territory. It may reasonably be expected that the sale of timber alone will recoup no small part of the expense of carrying out the project.

We take it for granted, that an ordinary iron railway is meant, the wooden one, projected many years ago by the Maharajah, having come to nothing. We saw wooden railways on some of the Queensland sugar works, but we noticed, that, in consequence of irregular tear and wear, many portions were covered with iron hooping. For temporary purposes even green wood might answer and does answer in North America, but in tropical climates the wood rapidly warps. A good iron railway run through the vast forests of Johore would serve not only for the conveyance of timber to the shipping port but for opening up the country to cultivation.

Mr. Newton selected twenty specimens of wood for examination, of which, he states, eleven are in constant use. The first on his list is known in Malay as SERIAH, while botanically it is classed as a *Hopea* :—

The Seriah is a tall handsome tree probably belonging to the genus Hopea of the natural order Dipterocarpaceæ, an order of great forest importance as containing such good timbers as the "Sal" of India—and most of the balsam producing trees of the Malayan Archipelago. Seirah has not as yet been botanically named although it has been in use for a considerable time, and formerly was found in abundance in the Malay Peninsula and Islands.

It is now becoming scarce, all traces of it near the banks of the rivers having disappeared, the Chinese sawyers seek far in the jungle for it, and fell and cut it up into planks on the spot. The wood resembles coarse cedar in grain and is of a light red colour. It is much used in house-building for joinery work. It is not suitable for beams or joists and is rarely used for that purpose.

Besides the light red wood described, there is another kind of Seriah in frequent use which the natives call Seriah Batu or Sama. It is much closer in grain, heavier, of a dark red colour, and far superior to the ordinary Seriah. It is not so abundant as the other kind but is much appreciated in house-building as it is admirably suited to joinery work. It has considerable transverse strength and is sometimes used for beams and joists in sheltered positions.

Both kinds of Seriah are employed for making furniture, and large quantities of the light red kind in the form of planks are exported to China, India and Australia. Next comes what the Malays call DARROO, or rather, because of its abundance, DARROO-DARROO. Botanically it is classed as *Apodytes species*, belonging to the natural order *Olacineæ*. The family contains nineteen or twenty Indian genera of trees, shrubs and climbers which are of little use with this single exception of a most useful aromatic wood. It is suited for sheltered situations, or as posts in the ground. It cracks if exposed. No. 3 in Mr. Newton's list has the Malay name of BALLOW, but no botanical equivalent is given. As this timber is said to have been used in the Colombo breakwater, we quote the description given of it :—

Unfortunately this wood has not been scientifically determined. It is a fine, large forest tree, growing to a height of 60 or 100 feet, and a diameter of from 3 to 6 feet.

The wood is greatly esteemed and is procured principally from Johore, Borneo and Pahang. The great demand for this fine timber has caused a scarcity which must continue as it is a slow-growing tree. It is much used in Singapore for joists and beams and for all purposes where strength and durability are required. It is of a light brown color, the shade of which deepens with exposure to the air. It is a close-grained, tenacious, hard, heavy wood, but is not difficult to work.

It has been called Johore Teak, although not belonging to the natural order verbenaceæ. Why it has been so named it is not easy to ascertain except that perhaps it has a resemblance to that esteemed timber.

Plants of this tree are readily obtainable, the seeds falling round the parent tree in large numbers, and as it possesses so many good qualities it should be systematically planted. An inferior class of wood, which is miscalled Ballow, is now being furnished by Chinese saw-mill owners in Singapore. Although possessing some of the characteristics of genuine Ballow, this wood cannot be compared to it in point of durability. The difference can be immediately detected by the colour which is too light for real Ballow.

Large quantities of Ballow have been exported to India, Australia, China, and some to Ceylon, where it was used in the construction of the Colombo break-water.

We referred to Mr. Kyle with reference to the concluding statement, and this gentleman tells us that he has searched the records of the breakwater in vain for evidence that ever "Johore teak" was used on the work ; "but," Mr. Kyle adds,

"I find we used a lot of jarrah from the Australian colonies and it did not do much good, as it will not withstand the sun like our satin or mililla woods. There is not a timber extent will resist the *Teredo navalis*, far less will jarrah or Johore in my opinion. For land work and general strength and durability in and out of season, nothing can touch the good old teak from Moulmein; and for rough tear and wear and use in the sea, the native satin and milila are the best we have."

The testimony borne to the value of the satin and mililla woods of Ceylon is very important, from an authority so experienced and careful as Mr. Kyle. As regards Australian jarrah, it is very disappointing to be told

that even this splendid hardwood will not resist the *teredo* of the Indian seas. In the Pacific the insects may not be so plentiful or destructive, or a good deal may depend on the age or seasoning of the wood; for conspicuous in the Melbourne Exhibition of 1880-81 was a magnificent slab of Western Australian jarrah which was stated to have been taken uninjured out of a jetty forty-two years old. No. 4, Malay TAMPINNIS (*Sloetia sideroxylon*) is described as one of the highest qualities of wood obtainable in the Straits. Amongst its good qualities is that of effectually resisting the attacks of white-ants. Mr. Newton states :—

As a wood for use in a tropical climate it cannot be excelled, but it is now rare and difficult to obtain, and even then is found to be far inferior to the old wood.

There is ample evidence and experience of the admirable qualities of this wood. Amongst which it may be noticed that in opening up and repairing the roof of the Town Hall, Singapore, in 1879, it was found that the whole of the rafters, king posts, queen posts, struts, and purlins were of Tampinnis. The cause which led to the opening of the roof was the destruction of the tie beams, which were of Kumpas, by white ants. Although these were without exception completely ruined by the ravages of that insect not one piece of Tampinnis was touched and the whole of the timbers were used in the construction of the new roof. At the time the repairs were made the Town Hall was about 20 years old.'

Another example of the remarkable durability of this wood was revealed in the rebuilding of Crawford Bridge, Singapore, when the old wooden structure was replaced by an iron girder bridge supported on screw piles. On removing the main timbers from the old bridge they were almost all found to be Tampinnis, in excellent condition. The bridge cannot have been less than 30 years old.

The wood is of rich brown colour and very close grained it is lustrous when cut either across or with the grain. It takes a splendid polish and when prepared in any way for use strongly resembles Mahogany.

It is quite clear that in forestry operations in the Straits (and in Ceylon also) special attention should be devoted to the propagation of this valuable tree. MIRABOO (*Afzelia Palembanica*) is a fine furniture wood. BILLION, not botanically determined, found in low swampy forests on the banks of rivers, is described as the most lasting of all the Malayan forest trees. It is difficult to work, except into shingles, and is sometimes called ironwood :—

And is greatly appreciated by the natives of Borneo, who use it for piles and joists for their houses. In Singapore this wood is generally used for the planking of bridges, for landing places, and for posts and railings, as it effectually resists the attacks of white ants, and will bear exposure to the weather without deteriorating. MIRAMBONG, not botanically described, is used for all engineering and building purposes. No. 8, BINTANGORE or POON (*Calophyllum inophyllum*) is well-known in Ceylon, belonging to the gamboge family, (*Guttiferæ*. The tree is used extensively for Malay house-building and for ships' spars Growing close together in jungles bordering the coast, the trees grow branchless to a great height. The KLADANG (*Artocarpus species*) may be identical with or very closely allied to our *Del*. It is thus described :—

This tree yields a fine light yellowish brown timber, when fresh cut, which bends easily and is useful for planking vessels as it stands well in water and is buoyant. The trees grow to a height of 60 or 70 feet and diameter of 2 to 3 feet. It is used in Malacca for house-building. The wood is close-grained and takes a fine polish, but turns dark coloured by exposure to the air. KRANGIE (*Dialum indicum*), is described as

One of the hardest, heaviest and most lasting of all the timber trees of the Malay forests. Like all hardwood trees it is of slow growth. It has been in great demand for many years past for export to China, but it is now scarce and expensive.

The tree itself is tall and handsome, and is frequently to be seen growing to a height of 60 feet and a diameter of 4 feet. It has no special locality, and is generally found in clumps. The Malays have given up felling this and other hardwood trees to the Chinese who transport it to the Singapore market in tongkangs. The fruit is edible and the leaf small like the tamarind, to which tree Krangie is closely related.

Krangie is referred to by Balfour who says "This is a handsome tree of slow growth but attains a great size. It is not a tree common in forests, but is generally met with in gardens, where it has been planted." The wood is hard, dark coloured, durable and often finely veined. It is used for furniture and building purposes.

KUMPAS, not botanically described, was in great request until the ant-eaten timbers in the Singapore Town Hall revealed its true character. LAMPONG (*Hedycarpus cauliflora*), seems to be an impostor like SERIAH, but does not, like that tree, belong to the EUPHORBIACEÆ.

KUYU KLAT is the Malay name of *Eugenia Zeylanica*. The *Eugenias*, including the jambu, are very common in Ceylon. Of this kind, it is said :—

The wood is used for ordinary building purposes. It is not very highly esteemed, but still is possessed of fair average transverse strength. It is close-grained, durable, and not much more difficult to work than darroo.

The mangroves of the Straits would seem to be more useful than those of Ceylon, if we may judge from Mr. Newton's account, under BUCCO, Malay (*Rhizophora species*) :—

The so-called mangrove swamps which are found along the shores of most tidal streams in the Malay Peninsula, are composed of two or three different species, the chief of which are, however, (Rhizophora mucronata,) (Rhizophora conjugata,) (Lumnitzera coccinea) and Bruguiera species. This most useful wood, which is always used in the form of piles, is abundant and easily procured. The mangrove tree grows luxuriantly in all salt water or tidal creeks with muddy banks. The piles can be obtained as large as thirty feet in length and ten or eleven inches in diameter. They are used in almost all engineering or building operations where it is necessary to make a pile foundation.

DAMAR LANT (*Canarium species*) is a family of large resinous trees, which, abound in Ceylon as well as the Straits. Mr. Newton states :—

This is one of the Malayan forest trees, which is much appreciated in Penang, where it is plentiful, and greatly used in house-building. It is possessed of great transverse strength and stiffness and can be obtained in large sizes. It is admirably suited for beams and joists. The colour is light brown and the wood is very close grained and lustrous.

RASSAK (*Vatica species*) :—

This wood is obtained from the South East coast of Sumatra and the neighbouring islands. Lately very large quantities of it have been used in the construction of a new wharf for the Borneo Company, Limited, in Singapore. It can be obtained in lengths of from 50 to 60 feet and sometimes 2 feet square.

By some Rassak is supposed to be the same wood as Damar Laut, but undoubtedly differs from it, and approaches more nearly to the Seriah in natural affinity. The specimens examined in the present series of experiments did not resemble each other either in grain, colour, or transverse strength, and Rassak is much darker coloured, not so close-grained as Darmar Laut and inferior to it in toughness and transverse strength.

DAMAR PUTIH is not scientifically identified, but it ought to be looked out, for Mr. Newton states distinctly that it is not attacked by sea-worms :—

This wood is procured from the district near Langkat in Sumatra. The tree grows to a height of about 150 feet and a diameter of from 4 to 5 feet. By some Damar Putih is supposed to be the same as Ballow, and it certainly strongly resembles it. It is of a light brown colour and close-grained and heavy, but not difficult to work. It is well suited for piles as it is not attacked by sea worms. Large quantities of this wood are now used in Singapore instead of Ballow.

Tambaga, of similar origin, is similarly unidentified :—

It strongly resembles Tampinnis, but it is stringy and not so lustrous as that fine wood and must not be confounded with it. The tree grows to a height of 100 to 150 feet and a diameter of 3 to 5 feet. The wood is principally used for the heavier parts of wooden bridges and for piles.

Kapur Baroos (*Dryobalanops camphora*) must not be confounded with the true camphor tree :—

This tree is found in Borneo and Sumatra. It grows to a great height and girth. It is used for planking prahus and in house building and is justly much esteemed by the natives, who are very partial to it owing to its lasting and generally serviceable qualities. This tree yields the Camphor gum so highly valued by the Chinese for its supposed medicinal properties.

Finally, we have Bullow Bungah, not identified botanically :—

It is a large handsome tree, the wood of which is suitable for some kinds of furniture. It is scarce. In colour it is grayish yellow and in many cases prettily grained.

Following the list of timbers are an account of the mode in which the experiments were conducted and elaborate tables showing the results. Pieces of the woods, 3′ × 1½′ × 1½′ clear span 2′ 6″, were tested with weight at the centre. The breaking weight for one specimen of Darroo was so high as 1,836 lb. ; Ballow 1,264 ; Tampinnis 1,850 ; Miraboo 1,374 ; Kladang 1,286 ; Krangie 1,656 ; and so forth. There are notes as to toughness, fracture, deflection, &c., interesting mainly to scientific or practical men, who can, no doubt, obtain copies of the work. We can only give the more popular portions. We may say, in conclusion, that we have been greatly impressed with the enormous timber wealth of Malaysia and the Eastern Archipelago, and the importance of its being cared for and properly utilized for the benefit of the world, instead of being recklessly sacrificed to the greed of Chinese speculators or the waste of gambier growers. For this reason we are glad that so much of Borneo and New Guinea have passed under the rule of civilized nations who will not neglect prudent forest conservation any more than encouragement to legitimate planting enterprize. Mr. Newton's researches and the mathematical tables and diagrams furnished in his work will be valuable guides to distinguishing really valuable timber trees from the mass of useless vegetation which abounds side by side with such timber.

COFFEE, TEA AND CACAO ROUND KANDY.

Kandy, March 25th.

Roseneath is a sight of beauty with snow-white richly-perfumed blossom such as is now becoming rare. While tea grows anywhere, cacao only in select places. On Gangwarily the plants are magnificent, and Pallekelly was a most pleasing surprise considering the drought. So on Anniewatte and other places around Kandy. *Helopeltis* is little feared now. The late showers have freshened up all Nature, and Kandy is greatly improved, as the drives around are : it is certainly one of the most beautiful towns in the world.

TEA PLANTING IN CEYLON:

COLONEL MONEY CRITICIZED.

(To the Editor "Ceylon Observer.")

Colombo, 21st March, 1885.

Dear Sir,—Whilst recognizing fully the benefits which Colonel Money has conferred on the tea industries of India and Ceylon, by his works on tea planting and manufacture, I do not think the remarks in his letter No. 1 which appears in your issue of the 16th instant, respecting tea planting in Ceylon, should, in the interests of our tea planters, be passed over without notice, as they are likely to mislead those who are not acquainted with all the circumstances which will, in time, probably place the Island in the first rank of tea-producing countries. Colonel Money is deservedly so high an authority in everything relating to the cultivation of tea, that I feel great diffidence in venturing to criticize any remarks of his, and I should not have thought of doing so, if he had not himself expressed his want of knowledge of many of the circumstances connected with the growth of tea in Ceylon.

In the third paragraph of his letter, he says :—"If Ceylon extends gradually, and not in the mad way it is doing now, we may yet see the day when the demand will overtake supply, and decent prices result." It is a moot point when prescience, energy, progress and self-preservation assume the character of insanity ; but if there ever were circumstances which would justify what the Colonel calls madness, they will, I think, be found in those which have been expatiated upon in the local press.

The experience gained by Ceylon tea planters, and recently made public, proves, that, as long as cooly labour in the colony is about 37 cents per diem, it is possible to cultivate, manufacture, pack and transport tea to Colombo for 26 to 30 cents per pound. Assuming, however prices may advance during the next year or two from exceptional causes, that the average of Ceyon tea in Colombo, two or three years hence, will not exceed 50 cents per pound. There will be still a difference of 20 to 24 cents per pound between cost and proceeds, and taking the average yield of the colony at the reasonable estimate of 350 lb. per acre, there would be R70 to R84 per acre as a return on the capital invested. When I say that tea planted during the past four or five years, and that which may be planted during the next year or two, has not, and need not, cost, with suitable buildings and machinery, on an average more than R200 per acre, I think few planters will say that I am putting the cost at too low a figure ; but if R50 to R100 is again paid for waste land, and if palatial buildings are constructed, and the most costly machinery put up out of capital, then Colonel Money will be right in accusing us of that madness, which has contributed so much, in the majority of cases, in recent years, to the unremunerative cultivation of tea in India. It will be admitted the returns of R70 to R84 per acre, which are equal to 37 to 42 per cent on capital on the above bases, are ont such as would discourage progression, especially as we know that it would not be under the influence of inflated prices, but of such a low range as to lead to a gradual reduction in the supply from our chief competitor, and serious losses to a very large number of Indian planters.

In the fifth paragraph Colonel Money somewhat insinuates that Ceylon planters are greedy, and foolish, in taking all that their climate and cultivation gives them, and points to Indian planters as paragons of prudence and self-denial, for "they give the plant a rest, a holiday for three or four months." I suspect human nature is the same in India as in Ceylon, and that the Indian planter would, if he could, follow the example of his Ceylon brother, and make hay whilst the sun shines.

If tea plants require rest as Colonel Money says they do, manuring will certainly not give it in Ceylon; on the contrary, in our moist climate, it would, and does, increase the number of flushes, and to refrain from plucking them would only necessitate the more frequent use of the knife, which, think, is already too severely used to force the yield. The large yields obtained here are, I suspect, the result of our having planted descriptions of tea which in our climate give large heavy leaves. When prices of tea fall below 26 to 30 cents per pound in Colombo, maxims of

prudence may be preached with success; but, until then, all that the planter has to do, is by good cultivation and udicious pruning to keep his plants in a flourishing and healthy state and thus stave off sickness and exhaustion. But Colonel Money himself furnishes us with a reason why we should get as much out of our plants as they will give whilst they are young he says:—"In my opinion the excellence of Ceylon teas is in a measure due to the fact that this gardens there are young."

In the 7th paragraph he expresses an opinion that "Ceylon is going too fast ahead, and its eventual success will not be diminished, nay increased by caution"; and in the next paragraph he says that 'large areas quickly planted are not always planted well." If Ceylon had been a new and unopened country like Perak, or North Borneo, this opinion would have been correct; but he forgets, that, when tea planting in Ceylon was proved to be not only profitable but successful in every respect, there were on the spot all the materials for extending it, on a very large scale, at the lowest possible cost, and in the most efficient manner: there was an army of intelligent superintendents with ample time at their disposal, who, by long training in a cognate industry, had nothing to learn in the mere work of planting tea, and were therefore most competent to extend rapidly the cultivation of a product which was proving itself capable of rescuing the agriculture of the colony from irretrievable ruin. There was agood supply of organized labour of the best sort, land in abundance belonging to the failing industry, and other land which could be bought at R10 per acre, and all that was required was seed for nurseries. When this was procured from India there was nothing to prevent the colony going ahead in a way which might have justified words of caution; but impecuniosty rendered them unnecessary. With all the encouraging prospects and almost unlimited energy, intelligences and materials, it has taken five years to plant 80,000 acres. I have no hesitation in saying that with the prospects of success, the little risk involved in its cultivation after estates are formed, compared with the cultivation of coffee, if capital had been available: not 80,000 acres but double that quantity could have been economically and well planted during the past five years. I do not say that the 80,000 acres has all been judiciously and well planted; but, where it has not been properly and wisely done, it was not owing to the want of knowledge but to the want of cash; and if cheaply-planted land will not yield enough to pay cost of manufacture, plucking, etc., the loss by abandonment will be very little.

I ignore the question which is frequently raised as to whether it is wise or prudent to plant large areas of perennial plants in view of risk of loss from disease or destruction from insect pests, or the possibility of extended cultivation leading to over-production and consequent unremunerative prices for the products, in the distant future. Such considerations for good and obvious reasons never have nor ever will act as deterrents or outweigh present encouraging prospects. I see no reason, therefore, why Ceylon is to pause in its onward course as long as prices (which are so low as to curtail supplies from competing countries) are remunerative, and likely to continue to be remunerative to the Ceylon planter.

If Indian tea planting was not weighted with high cost of plantations and excessive cost of management, I have no doubt that prices, which pay us well, would also pay the Indian planter; for, I imagine the cost of cultivation, manufacture, packing and transport to Calcutta is no more than it is in Ceylon. Ceylon need not enter into a race of competition with India: let each paddle its own canoe, but, if a vacancy has to be made for the 50 million pounds which will in time be exported from this island, it will I think be filled from a decrease in the supply from China, if the duties on exportation in that country are maintained at 2½d per pound.

However cheap labor may be there, it cannot compete with Ceylon (as is proved by the gradual falling-off in the export) as long as the duties on exportation amount to as much as 50 per cent of our total cost of production.

Colonel Money is not well up in political economy: he wishes India and Ceylon to limit their production, in order that consumption may overtake it, and thus cause an advance in prices; but forgets that such a result would enable China again to flood the English market with its cheap common congous, which are now only being slowly driven out by prices which do not cover cost of manufacture, packing and duties, to say nothing of remuneration to the grower.

The safeguards of Ceylon planting would be that neither the cost of production, nor the value of the produce, should be higher than they now are. An average of 1s 2d per pound, aye, or even of a shilling, will pay us well enough, whilst it keeps the prices of common China congou at a curtailing point.—Yours truly,

T. P.

PLANTATIONS IN CEYLON AND MAURITIUS AND THE O. B. C.

I have been favoured with a copy of the 7th proof of the Prospectus of the "Oriental Bank Assets Company," but, as it is intended only for private circulation and an 8th proof is already being prepared by the printers, it is obvious that this does not embody the definitive scheme and that I am not at liberty to publish it even if it did. Still I have permission to make known the general principles and even some of the details in regard to which there is not likely to be any material change. The liquidator proposes to transfer the following assets to the Company subject to the sanction of the Court of Chancery:—

1st. The Bank premises in London, Bombay, Calcutta, Columbo, Kandy, Galle, Jaffna, Mauritius, Madras, Shanghai, Yokohama, and Kobe, together with the office furniture, etc., which are valued at £310,000.

2nd. Certain assets, mortgages and claims in and connected with Ceylon, which on 3rd May last, according to the Bank accounts, taking the rupee at 20d, amounted to £326,000.

3rd. Certain estates, mortgages and claims in and connected with Mauritius, amounting in like manner to £1,360,000, making a total of £1,996,000. For these properties and claims the liquidator has provisionally agreed to accept £1,625,000 and to pass to the credit of the purchase all the sums paid on account of the calls on shares, which amount in all to £1,500,000, but are not expected to produce more than £1,100,000. In exchange for the liquidator's receipts deferred shares will be given, and it is proposed to issue preference shares carrying a 6 per cent cumulative dividend to the extent of £500,000 in £25 shares and debentures bearing 5 per cent to the extent of £300,000, so that, if these were fully subscribed, the Company would have in hand £275,000 after satisfying the purchase consideration of £1,625,000. But it is provided that the liquidator shall be repaid his outlay on the estates and refund the proceeds of sales made by him, which would doubtless involve considerable further payment by the Company. There is no schedule or other particulars of the Ceylon properties, the value of which is much less than was generally anticipated by outsiders, but their prospects are very favourably referred to. Thus it is said that the estates in Ceylon are already showing a surplus, and the latest advices, from a reliable source, are to this effect:—"The Ceylon estates are improving greatly in value and are now giving good returns. Not only are they paying their way, but they are yielding handsome profits, and, if the old shareholders can save them out of the wreck, they will be compensated in the next year or two. The success of our tea enterprize is now attractiug capital to the island, and it is generally thought that there will soon be a great demand for well-cultivated estates such as those of the old Bank." Then fol-

lows a long quotation from the columns of the *Ceylon Observer* regarding the rapid extension of the tea industry and the advent of a new era of prosperity for Ceylon. The draft prospectus goes on to state that arrangements have been made for the effective and economical management of all the estates until such time as they can be advantageously realized, which in the case of Ceylon, if deemed expedient, may be at a comparatively early date. Arrangements have been or will be made for letting the Bank premises at a rate more than sufficient to pay the debenture interest, and so far all looks promising enough but the most remarkable thing about the document is the conspicuous absence of all reference whatever to the prospects of the Mauritius properties, and, seeing that they are set down in the valuation at just four times the amount of those in Ceylon, the most casual reader cannot fail to notice, that, whilst considerable space is devoted to the one, absolute silence is maintained as to the other. I suppose, however, that this is one of those cases in which silence is golden, because candid speech would be detrimental. It is obvious that the Ceylon Company's estates are not included in the scheme, as was at one time reported.

Some sensation has been caused in Mincing Lane by the publication in last week's *Truth* of an article upon the relations between produce brokers and merchants and the influence upon the trade generally of the disastrous losses sustained throughout the last year or so. Whilst it is admitted that there is a certain amount of truth in Mr. Labouchere's assertions and the criticism founded thereon, yet there is a general complaint that the statements are far too sweeping and exaggerated and, therefore, unfair; but after all this is only characteristic of the writer. The brokers especially are up in arms at the unfavourable light in which they are depicted, and you will not be surprized at this when I quote as follows:—"The fact is that the Mincing Lane broker has a good deal to answer for as regards the present state of things. His cry has always been for business, and many a merchant has been led beyond his depth and induced to embark in hazardous speculations, by that unscrupulous adviser. The more produce is bought, and the larger the turn-over, the more brokerage for the broker. I do not say that there are not very honourable exceptions, but, on the other hand, there are some whose losses are richly deserved. Many Mincing Lane brokers also act as bankers to their clients by advancing on produce, and that is one of the subtle means which enables them to secure nearly the whole of the business of such firms. Once well in hand, the borrower has to pay through the nose for the accommodation, and the screw can be turned on whenever expedient. Then there is the unfortunate outsider with a turn for speculation in produce. When he falls into the hands of the broker, he is almost certain to be fleeced; and, although he may make some profits at first, he is sure to be the hindermost whom a certain wicked party takes hold of." Now, if one substituted *stock* for *produce* brokers, there would be a great deal more truth in what is here represented as their *modus operandi*, though there are a great many exceptions amongst them also. The great bulk of Mincing Lane brokers declare that of late the position has been too often exactly the reverse of that described above, in that they have had to do the work, find the money, and *bear the loss*, if any accrued, owing to the inability of so many operators in produce lately to take up their warrants when the prompts expired or to meet the difference on a re-sale; whilst, on the other hand, if the ventures turned out successful, their clients pocketed the profits, leaving them only bare brokerage and interest.

THE PROPOSED INCREASE OF THE DUTY ON INDIAN TEA.

The Indian Tea Association, with that promptitude which the interest they conserve demands, has sent the following memorial to the Government of India:—

Sir,—I am directed by the General Committee of the India Tea Association to inform you that their attention has been drawn to a telegram, dated London, March 6th, which has appeared in the daily papers, to the effect that the *Times* urges an increase of three pence on the present customs duty of six pence per lb on tea.

It is possible that this recommendation may not lead to any practical results, but the Committee would wish to bring the matter to the special notice of the Government of India in the hope that, if the Government should agree with the views held by this Association, steps may be taken for protesting against such a blow to the tea industry as the proposed increase of duty would undoubtedly cause.

The Committee think it almost unnecessary to remark that the proposed measure would probably add but little to the price of tea to the consumer, the burden falling principally upon the producer, whose profit is already reduced to almost the lowest possible point compatible with a continuance of his working.

The Committee would beg to point out that the present position of the tea industry is such that any further decline in prices would have a most disastrous effect. Prices of Indian teas at the close of 1884 were the lowest ever recorded, and though there has been some improvement since then, it is feared that the results of last year's working will show a very poor return on the capital invested.

It must be remembered, too, that upon the prosperity of the tea industry depends the position of thousands of natives of India who are at present employed in the trade, and who would probably be reduced to great privations if anything were to affect the continuance of their employment owing to the closing of tea gardens.

Looking, therefore, at the probable effect of an increase of the duty, and at the very serious consequences that would result to all engaged in the Indian tea trade, whether Europeans or Natives, the Committee trust that the Government of India may be pleased to do all in its power to prevent the adoption of such a measure.—*Indian Planters' Gazette.*

NOTES ON PLANTING AND PRODUCE.

(From the *Home and Colonial Mail.*)

In their circular of Feb. 17th, Messrs. Reinach and Nephew say of the tea market:—"Whatever may be the future course of the market in general, it stands to reason that with the limited stocks of Congou we are working on, certain grades will become scarce, and will probably show a further improvement between this and the end of the season. So far this firmness has not been caused by any increased demand; on the contrary, the home trade has only been operating sparingly, and owing to the increased duty in Russia, the demand for that country has been considerably smaller than usual at this season of the year. The strength of the market is mainly caused by the firmness of the importers who have withheld a large proportion of late arrivals, and only put up a limited quantity of tea at auction without reserve. It is true the arrivals from this to the end of the season will now be very limited, but the bulk of the unsold teas are in a few hands, and this itself constitutes a certain danger, the trade never knowing at what moment one and the other holder will become a seller, the more so as we are rapidly approaching the time when the chief aim of every one connected with the trade is to have as little stock as possible. On the other hand, there can be no doubt that the statistical position is exceptionally strong. Now that the China season is virtually finished, and that we can gauge the probable arrivals from India within a few millions, we can form a fairly reliable estimate of the stock of old tea we shall hold at the end of June. If deliveries continue at the same ratio they were last year, we shall find ourselves with a stock at the end of the season which will barely be equal to two months and a half consumption. In ordinary times this would be sufficient reason for a strong market, but when we take into consideration the political situation, we cannot be astonished at holders taking a sanguine view of the future."

A new process of sugar refining, was, according to the *Electrician*, recently tried in America, in which the principal

agent employed is electricity. The cost is said to be not more than "3s 4d per ton, and the result a hard sugar of almost absolute purity without any syrup, whatever." As the cost of refining, under the present re-melting processes, varies from £3 to £5 per ton, the above alleged discovery would be a startling one if it were true.

COFFEE PLANTING AND SCOTCH FARMING.

(By an ex-Ceylon Coffee Planter.)

WHY OLD COLONISTS ON RETURNING TO THEIR NATIVE LAND TAKE TO FARMING—GOOD TENANTS—MANURING—LEAF-DISEASE NOT TO BLAME FOR ALL THE MISCHIEF TO COFFEE—ARTIFICIAL MANURES—BAD PLANTING—WEEDS—DEPRESSION IN COFFEE PLANTING AND FARMING—TEN YEARS AGO AND NOW.

The question has often been asked, why is it that so many men who have lived in the East, on returning to their native land, adopt farming as a profession. This question has never been answered to my knowledge, but the following are the reasons, as far as I have been able to gather them from others, as well as from my own experience. That merchants in the East work far harder than men of the same profession do in England, and planters work harder than farmers do in Britain, I think there can be no doubt; and yet one never hears of them crying out for an eight hours movement: so far from their doing so, work becomes such a part of their existence, that idleness is to them the hardest work of all. So it comes about, that, when a tea-merchant from China, a broker from India, or a planter from Ceylon, gives up his work abroad, to settle at home, idleness becomes so irksome to him, that he looks around for something to do, and invariably his choice falls on farming, it may be as the proprietor of an estate, or it may be as a tenant: this of course depends on the means at his disposal.

A farmer is virtually his own master, and can do anything that he may wish, subject to a few restrictions mentioned in his lease, as to the course of cropping he is to adopt, and the quantity of manure he has to apply. This is the great charm of a farmer's life to men from the East, who have been accustomed to have themselves obeyed in every respect, and this is the chief reason why they adopt farming as a profession. Whether it is a profitable business for them or not is a different thing, but, judging by the many cases I have known, I consider it a very profitable thing for a proprietor to secure some of these returned self-exiles as tenants, for they are always ready to spend money in doing good to their farms, and are generous to the soil, knowing that only by kindness can they expect good returns from the earth.

It may seem anomalous to compare planting in Ceylon with farming in Scotland, but yet I find old planters, now farmers, applying the knowledge they gained, on the coffee estates of Ceylon and India, to the work of their farms here, and in nothing more than in the vexed question of manuring. In the palmy days of the coffee enterprize in Ceylon, manuring became a mania, planters were reckless of prices, and apparently only strove to discover a manure that would put more crop on their trees, regardless whether it injured the trees or not. Castor cake, coconut poonac, rape cake, &c., were all tried, and in many cases the result was good for the one year, but then something happened and *Hemileia vastatrix* had to bear all the blame. Truly, leaf-disease was a virulent foe, but it was not to blame for all that it got credit for, and I am more confident now than I was ten years ago, that the artificial manures which were applied to the coffee bushes did more harm than good by forcing the trees to undue bearing only to make them collapse afterwards and made them less able to withstand any disease. It is well-known that liquid manure is conducive to finger-and-toe disease in turnips, and yet liquid manure is the finest that can be applied so long as it is accompanied by plenty of bulk. It may be remembered that those portions of coffee estates which lay handy to cattle sheds and cooly lines were the last to succumb to leaf-disease, and I think no one will deny that this was all owing to the bulky manure which was put round the coffee there. In like manner, I know land in Scotland which gets year after year large quantities of artificial manures either ploughed in or used as top dressing, but the result is most unsatisfactory, whilst other ground, poor sandy soil or reclaimed peat moss, which gets its regular quantum of cattle manure and bones, gives crops good enough to encourage farmers even in these depressing times. The usual quantities of manures that one is bound to apply, according to one's lease, are 14 yards of farmyard dung and 500 cwt. of bone meal per acre during a five years' course. This is apparently a large quantity, but there are many farmers who are not satisfied with this, but apply considerably more, and I have not yet heard of a single instance in which the farmer who did so, regretted his kindness to the land. This has been my own rule, and during the last three years in which I have been engaged farming my average crop of oats has been 40 bushels per acre, which is remarkably good if one is to believe what has been the farmer's outcry for the past three years, "the land is worked out," the more so when I find by reference to colonial statistics that oats in Victoria only averaged 22 bushels, in New Zealand 27 bushels, and in Tasmania 25 bushels, three countries blessed with an unlimited amount of virgin soil.

I do not for a moment mean to say that the experience which I gained of the effect of artificial manures on coffee had proved them to be not only useless but damaging but what I did learn was that artificial manure *applied by itself* was most injurious by causing any plant to over-exert itself and then to collapse; but when the same is applied along with bulky manure it is most beneficial. If one is unable to apply bulky manure, then it is far better to leave the artificial unapplied also. Having formed this opinion, I am in the habit of applying bones along with the cattle manure to my arable land, for no artificial manure ever tells better than bones. Naturally, the cattle manure on a farm in Scotland is richer than that on a coffee estate, for here the cattle consume large quantities of linseed and cotton cakes, besides oats, bran and salt; and manure from cattle fed on one ton of linseed cake is said by Sir J. B. Lawes, an eminent authority to be worth £6 10s, as compared with that where the cattle have only grass, and which is valued at 15s only.

Besides there being a similarity in the work of manuring a coffee estate and doing the same to an arable farm, there is also an opportunity of utilizing the knowledge gained abroad in the pruning and planting of trees, and here I may remark that I have never yet seen a properly pruned gooseberry bush, the British gardener having a prejudice in favour of "crows' nests" as we used to call them in the case of coffee bushes that had been badly cleaned out in the centres. Foresters also have a careless way of putting in young trees, and no wonder that the death-roll is so great, when every second tree has its root twisted upwards in the ground. An old planter can easily tell, by its sickly, pining look, a tree that has been treated in this way, but I have astonished many here by pulling up young trees, one after the other, and showing the roots twisted in a manner that prevented their growing.

In the matter of weeding, a dirty farm gives just as poor returns as a weedy estate, and it is a notorious fact that the farmers who are loudest in their complaints at the present state of depression, and who are the foremost at Farmers' Alliance meetings, have their farms in a disgraceful state with weeds.

There is still another point in which coffee planting and farming in Britain correspond,—I allude to the state of depression which we find both industries now suffering from. Who could have thonght in the palmy days of coffee, in 1874, what a decade would bring forth? Then, the bushel of parchment coffee was selling at R12·50, now it is only worth R8. Then, R1,000 an acre was paid for a good estate; now that same sum would buy many an estate in the island. Then, a planter had only to show himself either in a merchant's office or a banking-house, and mention his requirements, to be at once accommodated; but now, Ichabod—the glory has departed from him. Ten years ago, farming in Scotland was considered to be in a prosperous state, no complaints were heard, and yet, if one goes into figures, it will be found that prices are more in favour of farmers now than then. On referring to the books of my own farm, I find that in the years 1874, 1875 and 1876, oats averaged 38 bushels per acre, and sold at 16s per quarter, against an average of 40 bushels to the acre sold at 22s per quarter during the last three years. Grass-parks during the years 1874-76 let at an average of £1 10s 3d per acre; whilst the very same fields, under similar conditions, during the past three years, have let at an average of £2 9s 3d per acre. From the same source I find that cattle have remained just about the same in price, two years old fetching from £20 to £27 per head. The rental again has been reduced from £1 13s 6d to £1 5s 0d an acre, which also is in favour of the tenant. Under these circumstances, I fail to see why the cry of depression has been so great, when everything points to a more favourable state of affairs now than ten years ago. I fear I must again remark that the loudest in the outcry have their farms in the poorest condition and most overgrown with weeds—but, surely, this is the fault of the farmer and not of the land. COSMOPOLITE.

HOW A CHEMIST MAKES HIS TEA.

"How to make a good cup of tea" is a question very often propounded by the industrious house-wife. It has been often told how the Chinese, the Japanese and others make theirs, but we have never seen before in print how a chemist makes his "cup that cheers." The following is the method adopted by Professor Attfield as described in his "Water and Water Supplies." He says: "A solitary chemist in his laboratory boils water in a glass beaker, and when it has boiled about one minute he turns off the source of heat, drops in a teaspoonful of tea, places saucer over the mouth of the beaker, and for three or four minutes feasts his eyes on the slowly-falling leaves and the gradual coloring of the infusion from a pale sherry tint to a dark golden. He then decants the clear, bright fluid into another beaker, and, according to his wisdom, adds nothing, or sugar and milk, or cream, if at hand. A portion is at once poured off, cooled to drinking temperature, and enjoyed, and then another portion is cooled off and enjoyed, and, at proper intervals, others, the last being still a sipped draught of delicious hot tea. It is a great luxury to have a hot stock to the last. No doubt that advantage inolves the cooling of each portion before drinking, but for this operation there are those who, 'when nobody's nigh,' act on the belief that a saucer is the very thing; indeed, that it was originally made for this purpose. The semi-exhausted leaves are thrown away; a connoisseur never ventures on a second brew." We have several times pointed out that this is the proper mode of preparing a delicious cup of tea; but seeing that the housewife has not the appliance of a chemist's laboratory, still, if they draw the tea say, from ten to twelve minutes in the tin pot, and then draw it off in another previously heated vessel, they will have the same result.—*American Grocer.*

[If the tea-pot is heated before the tea is put into it and if the water poured over the leaves is boiling, and a cosy is placed over the tea-pot, the brow will be perfect in five minutes.—Ed.]

Tea at Vizianagram.—A gentleman wrote to us some time ago from Vizianagram in the Madras Presidency:—

"I shall be much obliged if you will give your opinion as to whether the rainfall I get here is sufficient for tea. The average is about 50 inches. Last year it was only 40, but that was abnormal. The whole fall is between 1st May and 30th October, none scarcely in the other months: perhaps about an inch each in November, December, January, February, March and April dry and hot; November, December and January cold and frosty: in fact in October begins to be rather cold. Reasonable facilities for irrigation, a good big stream never dry. Soil is pretty good, rather stony, and has all been previously cultivated by natives. I see in the *Tea Cyclopædia* (p. 268) that in Chota Nagpore, Kumaun and Kangra the rainfall is only 47·84, 48·61 and 42·61 respectively, but somehow I think this is not correct: what do you think? If this rainfall is correct there is of course no earthly reason why tea should not pay on these hills."

We regret that this letter has been so long overlooked. In reply to our correspondent's question we may say that tea could never pay with the rainfall he mentions.

Tea Withering.—The great want felt, no doubt, is a good withering machine, and it will, no doubt, come in time, but bitter experiences will probably be the results of experiments for some time. The conditions that attach themselves to withering the tea-leaf present so many difficulties that until the whole question has been gone into carefully, we cannot hope for any very good results. There are, no doubt, at present, many engineers, who could, in a very short time, produce a machine to wither leaf, but the point which, we feel sure, would be the stumbling block would be the doing so, without at the same time interfering with the fermentation and to attain a correct pitch of which forms one, of the many studies that engages a planter's attention during the manufacturing, and very often, through some small slip, resulting in disappointing results, all through the year. In considering fermentation, before we go further, we think that it is necessary to state that although withering is, we may say, considered by many as a separate operation, in reality it is not; for fermentation is going on in the leaf, whilst it is withering. What is fermentation then becomes the question, and we may say safely, we think, it is a decomposition of certain substances in the tea-leaf, which makes it more palatable. We think that but a thin line divides over fermented leaves and putrefacation. It is well known, that in order to produce a green tea, no fermentation is necessary, hence to force withering, or the primary stage of fermentation, by means of heated air, results in a hybrid, between a black or green tea, hitherto nameless; but which is easily recognized by any planter; as tea which has to be manufactured, this loses all "nose" or aroma, and liquors are wanting in briskness, although possessing, to all outward appearances a good dark liquor. Yet to all appearances, although it may seem an anomaly, a certain amount of heat is required, to get the best results. Given a high temperarture, dry air, and dry leaf, and any one can make good tea, so that the difficulty lies in a nutshell, and the question is, how is the humidity to be extracted from the atmosphere without using a perhaps too high temperature? and endangering your manipulated tea, instead of turning out a true black, if not a green, certainly a "pamoona" tea, for which, we are told, there is but a limited demand. In many parts of Assam, after a fortnight's continuous rain, the atmosphere is laden with humidity. The conditions vary from day to day and it is only by close observation and unrelaxing vigilance that the best results can be hoped for.—*Indian Planters' Gazette.*

AN ABSENTEE PROPRIETOR AND MORTGAGEE writes to us by this mail as follows:—"I am extremely glad to hear that you take a favourable opinion of the prospects of Ceylon. I am a firm believer in tea, and I have not altogether abandoned coffee, but believe that it will be cultivated with profit on many estates the owner of which has the means of carrying out high cultivation; but without manuring, it is idle to expect crops."

LEWIS & Co.'s TEA TRADE CIRCULAR, March 2nd, reports:—"Ceylon: there have been some fine parcels sold, which show a little improvement in quality on previous shipments, and they have commanded good competition. In some instances higher prices have been obtained owing to the small supply on offer." The highest price quoted in the Circular above 'Darjeelings,' 'Assams,' 'Chinas,' or, Javas,' is: "half-chests superbly choice Ceylon orange pekoe (beautiful leaf, ripe, rich full flavoured, delicious liquor; matchless) 2s 5½d."

CINCHONA ANALYSIS.—Mr. David Hooper, F.., C. S Madras Government Quinologist, has issued a circular stating that he undertakes analysis of all kinds of cinchona bark according to the latest and most exact method. The circular states that "Mr. Hooper is 'Herseira' medallist of the Pharmaceutical Society of Great Britain, and silver medallist in Practical Chemistry and Botany; he has been engaged for over three years as analytical chemist to two of the largest wholesale drug houses in England, and has received special training in Quinology under the supervision of Dr. J. E. de Vrij, C. I. E., K. N. L., at the Hague." We hope to give full particulars of fees &c. in a later issue.

TIMBER AND TEA BOXES FROM SCOTLAND.—A planter writes:—"As tea boxes are likely to be in great demand, what do you think of importing them from home? Say of good American pine, and the man just at hand to see about it, is our friend "Old Colonist" from Kirkland & Sons (or Co.) of Dundee, or Miller & Sons, Montrose. The latter, I see by the local papers, send out numerous cargoes of dressed timber to Australia every year, and the trade is increasing. Now they have machinery that could turn the article at the lowest cost, and I am convinced, if pine is suitable, it could be laid down at Colombo cheaper than can be produced locally. Old Colonist should get the dimensions, &c., and he might enquire at both the firms mentioned: they are two of the largest timber merchants in Scotland." What about pine affecting the flavour of the tea?

THE POSSIBLE EFFECT OF A WAR WITH RUSSIA ON THE PRICE OF QUININE.—A correspondent writes:—"Could you inform me through the *Observer* what effect the Crimean war had on the price of quinine or on cinchona bark, and, if bark is likely to go up or down in the event of a war?—H." A mercantile authority, to whom we referred the question, replies:—"I am sorry I cannot tell you whether the Crimean war had any effect on the prices of quinine, but, if it had, circumstances are now so different, that no comparison could be made, or safe deduction. I don't think an Indo Russian war would enhance the price of bark, because the Indian Government manufactures more quinine and febrifuges than would be required to dose the largest armies it can send into Afghanistan. There is little doubt, that, in consequence of the poverty of Ceylon planters, an enormous quantity of bark will be shipped this year to Europe. The railway receipts are more than 50 per cent in excess of last year from the 1st October, and low prices necessitates larger cropping to give the same amount of cash. The probable export for the year is evidently greatly under-estimated." Russia is a large purchaser of quinine in England, and used to have an agent there on purpose.

VOLCANIC AGENCY IN UVA.—With referenee to the assertion of a contemporary's correspondent about the evidences of volcanic agency beiog apparent near Fort MacDonald, an old Udapussellawa planter writes:—"I have never seen any indication of volcanic agency in our neighbourhood. I do not see the local 'Times.' King (of the Indian Geological Survey), D. Morris (a very competent geologist), and others have been over here, and it escaped their observation. The formation is purely primary, the strike from the north-east dipping to the south-west."

TEA MACHINERY.—Mr. Jackson, the well-known inventor and patentee of much approved Tea-preparing machinery arrived at Colombo by the S. S. "Nepaul" on March 26th, and is making, we are glad to find, a stay of some duration in the island, in order to test the working of improved machines in which he is interested, and more particularly of his new Tea Drier. Mr. Jackson has had special advantages in his career, first from his training as a practical engineer, and next beginning so far back as 1870 in Assam as a tea-planter. The preparing machines then in use were few and primitive. We need not recapitulate all that has been done since, and more particularly by Mr. Jackson himself, his Tea-roller being now generally acknowledged to be about the best available, the only fault we have ever heard connected with it being its cost. But if all that is said about the new Drier be correct in practice, it ought to spread Mr. Jackson's fame, even more than his Roller. This Drier was erected last year in the Jorehaut Company's Factory by Mr. Dalgarno, a representative of Mr. Jackson, who now accompanies him to start the first in Ceylon—and the result of the season's experience in Assam was that the one Jackson drier did as much work as seven ordinary Siroccos, and it is claimed better work too. In fact, Jackson's invention claims properly to be a machine, saving labour and working automatically, whereas Siroccos scarcely answer either end. The new drier

HEWAHETA CINCHONA.—The following is an extract from the letter of his London brokers to a Hewaheta planter kindly placed at our service:—

"The 'Gleuogle' shipment was very fine, and as the market had gradually improved for three sales, we were able to obtain long prices, that of 2s 8d to 2s 9d for the 8 bales renewed red shavings being the 2nd highest price which has been paid this year for succirubra bark. You are much to be congratulated on growing such bark, and we hope you have plenty more like it. The following is the analysis which may interest you:—

Quinine Sulphate... ...	5·25	per cent	8 *bales.*
Ciuchonidine	2·70	do.	
	7·95		

And the analysis of the 11 bales renewed chips was also good:—

Quinine Sulphate... ...	3·18	per cent	11 *bales*
Ciuchonidine	2·22	do.	
	5·40		

We commence this year with a stock of bark, which, though stillvery heavy, is 20,000 packages lighter than that with which we commeuced 1884, a reduction caused by the gradual cessatiou of imports from South America, consequent on the low prices current in the Londou market, and it seems probable that we may have a better range of prices this year than last, if Ceylon is to ship considerably less* than last year, as reported on all sides, and if there is no disaster like the Milan failure to disturb the market; for the prices now current are still considerably below what would pay a South American importer of uncultivated barks to continue importatious on any large scale."

*Wrong—and not justified by our estimates or remarks in January last.—ED.

THE PROSPECTS OF "TEA" IN THE UNITED KINGDOM.

We find in the London *Times* of the 6th March, under the head of "National Expenditure and Revenue," some valuable information of much interest to Ceylon planters at the present time. The writer begins by referring to the anticipated deficiency in the national accounts (even without counting on the chances of a Russian war) which Mr. Childers has to meet. A protest is entered against increasing the income-tax beyond 7d, or at the very most 8d in the £, unless in the emergency of a great war such as the one now pending with Russia. It is made clear, however, that there must be a resort under any circumstances to indirect taxation as well as to the income-tax, and we then come on a passage of special bearing on our own local legislation of last Session when, in contravention of both expediency and sound principle as we protested at the time, the Customs duties on imported wines and spirits were increased without any corresponding increase in our local excise on arrack. This is what the *Times* says :—

Were it not for the peculiar fiscal relation existing between the Excise duties on spirits and the Customs duties on spirits and wines, which necessitates the simultaneous alteration of both sets of imposts, the simplest mode of remodelling our system would be to raise the import duties on alcoholic liquors. But that plan is difficult of adoption, especially just now when a treaty with Spain which will alter the wine duties considerably is being discussed at Madrid.

To re-impose the duty on sugar is said to be "out of the question," and the tax on tobacco is supposed to have reached the limit beyond which the risk of smuggling becomes intensified. Accordingly there is only *tea* to fall back on, and this is how the subject of an increased duty is elaborately dealt with :—

The only article from which it would be possible to obtain a considerable increase of revenue without much inconvenience is tea. Of course, a proposal to raise the tax on tea would be furiously condemned by the advocates of a "free breakfast table," but, apart from mere doctrinaire outcry, there is no sound objection whatever to the measure. Assuming an addition of 3d per lb. to the present tea duty of 6d. per lb., we may estimate the revenue to be derived from it in the following manner, by aid of a table which will be found below.

In 1884 the average price of the tea imported was 11·78d. per lb. (in bond). The addition of 3d. would raise the price to at least 14·78d. per lb. Perhaps it would raise it even more. In order to be on the safe side, seeing that the stocks of tea in London are low, and that, owing to the Franco-Chinese dispute, there is some danger that our supplies from China may be diminished, we shall assume that the price will be raised to 15·29d. per lb., which was the average price in 1878. During that year the consumption of tea per head was 4·66lb.

At the middle of last year the population of the United Kingdom was estimated at 35,952,000 persons. We may safely assume that it has now reached 36,000,000, and therefore the total consumption of tea during the coming year, assuming the consumption per head to have been reduced from 4·87 lb. to 4·66 lb., would be 167,760,000 lb. It will be observed that this gives us a reduction in consumption of only about 4¼ per cent., which at first sight may seem too small. We venture to think, however, that this is not so, for there is good reason to believe that the price of tea had some time back fallen to a point at which diminution in the price had little effect in increasing consumption. Between 1869 and 1874 the price fell 1½ per cent., from 17·78d to 17d, and the consumption rose 16½ per cent. Between 1874 and 1879 the price fell 13½ per cent., from 17d to 14·68d, and the consumption rose 10¾ per cent. But since 1879 the price has fallen 19¾ per cent., from 14·68d to 11·78d, while the consumption has only risen 3½ per cent. The great increase in consumption between 1869 and 1874 may, of course, be largely attributed to the great advance in wages which occurred during that period, and also in some degree to the repeal of the tea-dealers' licences in 1869. In spite of falling wages consumption continued to increase during the period 1874-79, owing, doubtless, to the great decrease in price already mentioned. Since then, however, a much greater decrease in price has only produced a small effect on consumption, although wages are not lower on the whole, and are higher in some trades than they were in 1879. It is, consequently, unlikely that the consumption per head would diminish more than we have estimated even if the price were raised to the full extent allowed for.

We may, therefore, take the probable consumption of tea in 1885-6, supposing the duty were raised to 9d. per lb., at 167,760,000lb., which would yield a gross revenue of £6,291,000, not deducting repayments and drawbacks. It is not easy to determine how much should be allowed for deductions on this score, because the statements as to quantities imported refer to the calendar year, while the statements of revenue received, with which comparison might have been made, refer to the financial year. It would seem, however, judging from recent years, that they are trifling, and it would probably be safe to assume that the gross produce of the new duty would be about £6,150,000, or nearly two millions more than the revenue for 1883-4. From this, again, something might perhaps have to be deducted for increased charges of collection, but it could hardly be much. Considering the allowances we have made in the above calculations, we are disposed to think that about two millions is a fair *minimum* estimate of the yield of an additional 3d per lb. on the tea duty, which sum would be of great assistance not only to Mr. Childers in his present straits, but to all future Chancellors of the Exchequer.

The following is a statement of the population (estimated) of the United Kingdom in the middle of each of the undermentioned years, and the quantities of tea retained for home consumption in the same years, as given in Table 23 of the Statistical Abstract (in thousands—000's omitted) ; also the number of pounds consumed per head, and the price of tea per lb., deduced from the quantities and values as stated in Table 42 of the Abstract.

	Population.	Quantities. lb.	Consumption. per head.	Price Pence.
1869	30,914	111,796	3·63	17·78
1870	31,205	117,551	3·81	17·18
1871	31,513	123,402	3·92	16·44
1872	31,836	127,661	4·01	16·78
1873	32,125	131,881	4 11	16·67
1874	32,426	137,210	4·23	17·00
1875	32,749	145,327	4·44	16·73
1876	33,093	149,104	4·50	16·42

1884	5,952	175,000	4·87	11·78

The quantity set down as retained for consumption in 1884 is an estimate. The amount entered for consumption in 1884 was, according to the Board of trade Returns, 175,098,000 lb. For the previous years the differences between the amounts entered and those actually retained were very small, and they have lately shown a tendency to decrease, as the subjoined table shows (000's omitted) :—

	Entered for Consumption.	Actually Retained.	Difference. Amount.	Per cent.
1879 ...	160,652	160,432	220	0·13
1880 ...	158,570	158,322	218	0·16
1881 ...	160,226	160,051	175	0·11
1882 ...	165,080	164,558	122	0·07
1883 ...	170,813	170,718	32	0·02

Increase in Consumption per Head.

1869.	1874.	Increase.	Per cent.
3·63	4·23	+ 0·60	+ 16·5
1874.	1879.

1879.	1884.		
14·68	11·78	2·90	19·8

It will be observed that as a consequence of the addition of 3d per lb. to the duty, the annual consumption is at once expected to be affected to the extent of nearly 8 million lb. Thus for 1884, the total consumption of the United Kingdom is put at over 175 million lb., while if the duty were raised to 9d per lb. in 1885-86, it is calculated that only 167,760,000 would pass into home consumption. This is not encouraging to tea planters, more especially as trouble with Russia cannot fail to interfere with the tea trade with that country and with the Continent of Europe generally, comparatively unimportant as it may be. The only consolation for Ceylon and Indian planters is that apart from the China export trade being crippled, the commoner kinds of tea will be the first to suffer, and the advantages of this colony for the production of high-class teas at a moderate cost will become more than ever apparent.

PLANTING PROSPECTS IN THE WEST INDIES:

Mr. D. Morris and Mr. George Hughes.

We are glad to find that a more buoyant feeling is beginning to prevail throughout the West Indies regarding the sugar industry, and that many of our colonial contemporaries are taking a more sensible, and withal a more hopeful, view of the question. "Don't give up cane culture." This is excellent advice for the *Gleaner* to give the Jamaica planters, and we trust that every effort will be made by all who are interested in the industry to prevent the estates from going out of cultivation. It is well-known that owing to the long-continued depression of the sugar markets of the world many of the plantions, not only in the West Indies but elsewhere, are heavily involved. In face of the more favourable reports, however, continually coming to hand—reports of the growing dislike of the bounty system by the continental people, of failures and difficulties amongst those engaged in the beet industry, and of the likelihood this season of a smaller crop of beet—there ought to be little difficulty experienced in procuring the necessary advances to proceed. There is an abundance of money here now in the banks returning not more than 1 per cent. Surely there are amongst those who are lamenting the present state of things in England many who would be very glad to hold mortgages on sugar estates at a fair and reasonable rate of interest.

Mr. Robert Galloway, in a letter to the *Morning Post*, contends that, "for the success of cane sugar manufacture in the future, the planter must cease to be also the manufacturer; there must be one or more central factories in each of our sugar colonies, to which all canes from the different estates would be sent. Then, not only could all suitable machinery required be obtained, but the best skill and intelligence necessary for the proper purification of the juice and other manufacturing operations." We are aware that Mr. Galloway is a bit of an enthusiast on this question of "purifying the juice," but we have before us a pamphlet on the "Relative Positions of Beet and Cane Sugar," by Mr. William Russell, of Elgin, and it is interesting to note that he also contends that "those of the planters who are in a position to avail themselves of the very best appliances in manufacture might, under improved conditions of labour, look forward to times when they would hold their own against their formidable rival." Even in the present disorganized condition of the trade cane sugar has been fetching 1*l.* per ton more f. o. b. at Demerara than beet sugar f. o. b. at Hamburg, and as it has been proved that a larger weight of cane can be grown on a given area of land, and at a cheaper rate, than beet roots, and that the sugar contained in the sugar cane is of greater purity than is found in the beet, it is felt that the future of the sugar trade is in the hands of the planters, and that they will triumph over every difficulty if they will but give a little more attention to the industry than they have done for some time past.

Next to improved machinery and a more rational and scientific treatment of the soil, nothing can be more conductive to the success of West Indian sugar estates, as Mr. D. Morris pointed out in his lecture on "Planting Enterprise in the West Indies," delivered before the Royal Colonial Institute two years ago, than the introduction of new varieties of canes to replace or supplement those which have been so long and so persistently cultivated within the same areas. With the sugar cane as with all other plants, the continuous cultivation of the same kinds on the same lands, it is held must result in reducing their health and vigour, and consequently the quantity and value of the produce. Where estates have no nurseries, and tops for planting are taken from weak and partically abandoned canes, the general character of the cultivation, the Director of the Jamaica Public Gardens maintains, must be gradually lowered, even on the best soils, and as he rightly said, no plan can be recommended so likely to overcome this as the introduction from time to time of new kinds of sugar canes, which are the result of careful selection and cultivation in more favoured countries.

The *Quarterly Journal of the Geological Society*, just issued, contains some remarks on West Indian phosphates, by Mr. George Hughes, which were communicated at a recent meeting of the society by Mr. W. T. Blanford. From specimens of phosphates which have been brought under his notice, Mr. Hughes has found that under certain conditions it is possible for coral stone to be converted into phosphate of lime. Mr. Hughes' attention was first directed to this fact in the island of Barbuda, where he found a small vein, rich in phosphate of lime, starting from the bottom of a cave in the face of a coral cliff; but it is to the deposit found in the island of Aruba that he draws special attention, because, there the process of phosphatizing the coral has been in operation on a most extensive scale. The deposit is estimated to contain not less than 500,000 tons. It occurs at the extreme point or cape of a peninsula of coral; the headland is called Sierra Colorado (or red hill), and rises about 300 feet above the level of the sea and about 200 feet above the level of the coral that connects it with the island of Aruba. His opinion is, that when this hill existed as a small island, or "cay," and the coral reef between it and the then main island of Aruba was submerged, it was the resort of sea-fowl, and their excrement, like the bat-guano, containing soluble phosphates, caused the change in the rock upon which it was deposited. There is no trace left of the phosphatic guano upon the surface; but the solid rock is now rich phosphate. This phosphatized coral yielded from 78 to 80 per cent of phosphate of lime, and, so far as the deposit has been shipped as yet, the cargoes have tested over 76 per cent of phosphate. Other deposits of phosphate found in the West Indies (Mr. Hughes believes) owe their origin to direct marine deposit of bone, as, for instance, that of Curaçao. In the next island to Curaçao (Bonaire) he has seen the coral over an area of two miles to contain fossil bones and teeth scattered in all directions. The specimens exhibited at the meeting showed how these bones occur; and, had they been deposited in one spot, as in Curaçao, Mr. Hughes says "we should have been able to have worked a good deposit." Mr. Hughes, who is now in London, returns to the West Indies by the mail of April 17th.—*Colonies and India*, Feb. 20th.

ARECANUT CULTIVATION.

The interesting letter from Mr. Borron which the *Observer* published last week, (see page 791) deals with a product to which natives are directing increasing attention. In no sense can the arecanut be called a new product among the natives. It has always entered largely into their favourite masticatory—the betel-leaf, lime, and tobacco; and has in consequence been cultivated for centuries for domestic use. There is scarcely a native garden, but has a few arecanut trees in it, sufficient to supply the wants of its proprietors. These trees receive no systematic cultivation; nor are any large continuous tracts placed under the product by natives. We do not forget that there are *Arembas* or areca plantations among the possessions of well-to-do natives, especially in the Central Province, but these are generally of small extent, not often exceeding 4 or 5 acres, and more seldom still amounting to 10 acres. We believe the majority of trees are grown along boundaries. Partly through extension as an aid to a well-defined boundary, and partly from spontaneous growth at the foot of trees in village gardens, more arecanuts have been produced in recent years than are necessary for local consumption. The ubiquitous Moorman and the adventurous Chetty have not been slow in taking off the superabundance for export to the adjoining continent. A brisk trade goes on now in the article, as may be seen by a visit to boutiques in central villages or small town-ships. The remote villager now knows the nearest market for his crops. We believe there has been some extension in the cultivation of arecaunuts by villagers in consequence of this demand for exportation; but we fear this has not been quite so great as the activity in theft of the produce. The village gambler and drunkard have been quick to avail themselves of the fruits of the labours of their honester, but not too industrious, neighbours. Cases of arecanut stealing, and of accidental death by falling off arecanut trees at night are not uncommon; and, coupled with the precautionary thorns found on areca stems, tell of increasing appreciation by the light-fingered gentry of the growing demand in our bazaars.

Among the many blessings in disguise which the decadence of the coffee enterprise has brought in its train, is that the attention of Europeau planters has been directed to the cultivation of arecanuts, for centuries wholly in native hands. The interchange of views which the cultivation of this product by practical and scientific planters has led to, will no doubt enure to the benefit of the native, by suggesting systematic planting and cultivation. There are not a few Chenas and abandoned gardens, which might be profitably planted up with arecanuts; for although, in many cases, the cultivation of Chenas is resorted to, to ward off famine, or to supplement the corn produced by mud lands, in not a few cases their cultivation with fine grain is due to custom, and to the conviction that the land is unsuitable for a regular plantation. The sight of a continuous acreage under areca will doubtless, suggest the practicability and wisdom of going and doing likewise. We trust that this may be so; and it is with this object we draw attention to Mr. Borron's letter. Some of our readers might prove pioneers of a very promising industry in purely native districts, by paying greater attention to arecanuts, and thus encouraging their cultivation by the native peasantry. If there is the drawback that the plantation will not come into bearing until the sixth year, it is a drawback with which the native is already familiar by observation and experience. On the other hand, a grand advantage in the eyes of the ordinary peasant is that it will not require continuous attention or very close cultivation. Through the possession of uncultivated land, or land on which arecas can be grown without injury to the existing cultivation, and through being able to devote his labour to its cultivation, without detriment to his other avocations, the peasant proprietor can bring his holding into bearing at one-tenth of the cost that Mr. Borron gives; while natives who employ labour will certainly be able to do with half the sum named as necessary to bring land into bearing. So far as our observation goes, the tree affects shade, and thrives best in clumps of two or three so that Mr. Borron's distance of 10 ft. × 10 ft. appears a great deal too much. How closer planting may affect the crop, we cannot tell; nor would we be safe in pointing to the luxuriant growth and heavy bunches in native gardens in support of our view, because most of such trees are near dwelling houses, and have all the advantages of moisture and constant additions to the soil which such proximity gives. We are yet inclined to the view that 6 ft. × 6 ft. would be a better distance; but experience alone can decide this question. On this point, as well as on others regarding variety, yield, etc., we should like to hear from our native friends, whose experience and observation may be wider than our own. We believe the native variety is best suited for export owing to the closer grain of the nut the *Rata Puwak* being softer and principally used for mastication; but the Mysore and Sheriwadun varieties are spoken of as superior to ours, and commanding double, if not treble, the price of our nuts in Bombay. A netprofit of 50 or 60 rupees an acre is not to be despised in these days; for coconuts seldom yield as much as that, and cinnamon certainly does not at present.—Local "Examiner."

CEYLON UPCOUNTRY PLANTING REPORT:

THE BREAK-UP OF THE DROUGHT: ITS EFFECTS ON TEA—COFFEE ESTATES SOON TO BECOME A THING OF THE PAST—COFFEE AS A BEVERAGE—NATIVE COFFEE—BUG—CAPE-GROWN COFFEE—THE AMERICAN EVAPORATOR—PLANTING TEA ON SWAMPY GRASSLAND—A MORAL CHETTY—CACAO.

27th March 1885.

The showers which have been falling all over the country for the last fortnight or ten days have done a world of good, and everyone rejoices that the drought has broken up.

The brown rust, which was making our tea look as if it were made of bronze, is somewhat changed with the showers, and the rapid growth of the tender flush is now everywhere visible.

As to coffee, where it has any heart in it at all, it is trying to blossom, and really in some favoured spots the blossom is as fine as could have been seen in the best days of the old King. There is a tender interest about these wreaths of white, which are fast disappearing and will ere long be seen no more in the land where they were so common. The last song of the swan which sings its sweetest just when about to die is what occurs to the mind of the old planter as he looks upon the sheet of white, hears the hum of the bees revelling among the flowers, and inhales the heavily perfumed air. For has the edict not gone out to put in tea? In a very few years after this, the possibility of seeing such "a thing of beauty" as a field of coffee in full blossom will be impossible in Ceylon, and the planters will be taking to drinking the bean, since they have ceased to grow it, probably importing it from home. As it is, we hear wails of its already being placed among the class of luxuries. "Only a very small cup of strong black coffee once a day can I afford," says the tearful planter thus unfortunately situated; "at other times I must drink tea."

It is not an unlikely thing that the tea planter will take to cultivating a small patch of coffee close to his bungalow just for his own use, and, when this is so, really good coffee will be had on the hills, instead of the fearfully and wonderfully made stuff which in the years gone by used to be offered in the name of this beverage. How the traveller from the western world used to be taken in: at the fountain-head where the best might have been expected: the steam which issued from the planter's coffee pot was black as Erebus and bitter as gall. I met a planter once from the Wynaad district, who prided himself on being the only man who knew how to make a cup of coffee among the planters of Southern India. His method, however, was so elaborate and troublesome, that he had to give up active charge of his

estate, so as to perfect himself in the art! We all could not afford this, and with what envy I looked upon the man who need not be told how.

Native coffee even is trying its best to look well, and blossom like its better cultivated neighbour. I heard of a planter who more was than surprized with some coffee of this kind which was allowed to grow at its sweet will, untended and uncared for, in a semi-abandoned portion of his estate. Nothing like it has he seen for many years: so full was it of blossom. What it will come to, need not now be anticipated: there have been so many disappointments with this product, that one naturally inclines, in spite of any amount of promise, to expect nothing or next to it.

There are very few signs of bug—visible at least—where last season it cast its darkest shadow. Still a careful observer can find it clustering about the young shoots, and only wanting suitable conditions and a favourable environment to spread as rapidly as before, and ruin what it spared last year. There is an amusing paragraph in the *British Trade Journal* for this month relative to Cape-grown coffee for which that paper prophesises "an important future." And this is founded on the fact that a sample sent home was reported on by four reliable authorities, as having many characteristics of Mocha, and worth in the London market from 50s to 52s! An "important future" certainly. If the Cape can grow coffee to pay at these figures, there should be an exodus from Ceylon.

The American evaporator, which is being used on some estates for drying cacao and tea, is as usual being altered, and improved to fulfil the Ceylon planters' idea of what a perfect machine of that kind should be like. Double racks have been supplied, and runners all along the machine so as to allow the trays to move from end to end with as little expenditure of power as possible. But the machine would be very much better if it were built of light iron, instead of wood, there being with the latter always the danger of fire.

Planters who have been going in for digging and draining swampy grasslands for planting tea know what an expensive process that is, and how slow the work progresses. They don't care to say how much it costs, and seldom like to think of it. Yet, if I am rightly informed the expense of digging out the grass is almost unnecessary, for a bi-monthly weeding is said to be in time quite as effectual as the most careful picking out of roots. The constant removing of the grass has the effect of causing the roots to rot, and the tea plant, in the meantime, is not kept back very much.

Cacao, both in the lowcountry and here, is looking well. Now that the cold winds have ceased, and the showers have fallen, the bare leafless branches which looked as if a fire had passed over them, are bursting into a beautiful flush of young foliage and clothing themselves afresh. The trees are full of blossom, and what with the decrease of *Helopeltis* and the prospects of good prices at home, there is much encouragement to the grower.

PEPPERCORN.

THE CEYLON NORTHERN COFFEE (TEA) DISTRICTS.

MATALE, 1st April.

Having done the once grandly profitable northern coffee districts from Western Rangala to the Knuckles, the Kelebokka Valley, Elkaduwa, and Kandanuwara, my conclusions are that the utter extinction here of coffee is but a question of a very limited period of time, and that the rapidity and success with which tea is superseding the ancient product requires to be seen to be appreciated. There have been thunder-storms each day but very little rain, which is sadly wanted. The weatherwise Sinhalese predict six months yet of comparative drought, but the little monsoon and the big one will doubtless yield the moisture which the new product desiderates.

TEA BULKING AND PACKING IN COLOMBO

The opinion is spreading among some of our most thoughtful planters that the time is fast approaching when the store space in Colombo now lying unoccupied through the failure of Coffee, will be largely utilized in connection with the Tea Enterprize. It is said that notwithstanding the objection to the refiring and repacking of tea in Colombo, the work of sorting and bulking and the packing in large chests can be done so much more conveniently here that the practice is likely to be revived and gradually to increase in favour. One plan adopted in Rakwana was to send the tea down in air-tight barrels suitable for the shipment of plumbago for which purpose they were afterwards sold. As the only extensive experiment yet made was that by the Ceylon Company Limited in their Grandpass store, we asked for information from the gentleman who then managed their affairs and the following reply will be read with interest:—

"In reply to yours of 1st instant, yes, it was in my time that the experiment of sorting, final firing and packing tea was tried by the Ceylon Company, Limited, at their Grandpass stores. These stores have been recently let, I understand, to Messrs. Delmege, Reid & Co., but I fancy the firing apparatus may still be seen there unless Messrs. Delmege, Reid & Co. have removed it to make room for storage of oil &c. Financially speaking, the experiment was an undoubted success, partly no doubt owing to several windfalls we had in repacking the cargoes of more than one steamer laden with tea which came to grief during the period I am alluding to. But, apart from these windfalls, we did very well, and I believe my successor strenuously opposed the shutting up of this establishment, but orders from London were imperative. Many complaints were made of the tea being burnt, and it was gratuitously assumed that this happened at Grandpass, whereas such a thing was almost impossible there as we never did more than just *warm* the tea to expel any little dampness which it might have acquired on the way down or in store prior to being packed. With small breaks from gardens it was a great advantage being able to bulk several lots so as to make sizable breaks. Doubtless packing in Colombo has its disadvantages, not the least being the conveyance of the tea to Colombo in packages other than such as could be used when packed in the estate. We used zinc or tin-lined cases which were unscrewed after removal of the contents and then sent back to the estate. In this way we were able to do all our carpentering and tea making in Colombo, and freight to the estate on nails and tin lead was saved. When the tea arrived here it was immediately removed and transferred to large zinc or tin-lined bins which were easily rendered quite as airtight as any similar receptacles on the estates. We had sorting machinery to do the sorting, and, unless waiting to make up a break, sorting, bulking and packing were operations which permitted of being carried out with the utmost expedition.

"I am quite satisfied myself that no harm need arise to the tea in an establishment of this kind if properly conducted; but when the Ceylon Company, Limited, teas did not fetch the prices that

were looked for, a reason for it had to be devised and Grandpass Packing Establishment was made the bugbear. Since this establishment was given up, however, prices of the Ceylon Company, Limited, teas so far from being improved, have been worse than ever: and some other reason must be sought for. The curious part of it is that the teas, at least some of them, are by no means bad, and over and over again have I offered to purchase such teas here at prices which would have left a very fair profit to the Company compared with the London prices subsequently realized. However the Ceylon Company, Limited, is not singular in this respect, and I can quite understand novices in the art of tea making desiring to prove the value of their produce in the London market for themselves before accepting local valuations. Of course I have heard all sorts of rumours as to the cause of the poor prices realized by Ceylon Company, Limited, teas, but if I were to repeat them publicly I might lay myself open to all kinds of dreadful things too fearful to contemplate. One possible reason may be the rolling machinery in use by Ceylon Company, Limited. I believe they employ none but Nelson's machines in which the tea is put into a bag before being submitted to the pressure of the machine.

"On the general question, however, as to the advisability of finishing off the tea in Colombo in preference to doing this work on estates, much depends on how you look at it. I mean as to whether you put yourself in the place of the mill-owners or the tea-grower. If tea is to manipulated in Colombo, mill-owners must be allowed to make a fair profit on the operation, and the question is: can they do this and yet make it more advantageous for the grower to employ them than to complete the work on the estate? This requires a little consideration.—Yours, C. W. H."

PROGRESS IN TEA MANUFACTURE:

By ARTEMUS.

* * * Of course, as we produce so much more tea there is naturally a greater quantity of poor tea on the market; but that is not the point. The *proportion* of poor tea has increased of late years notwithstanding that the current low prices have brought about an extra amount of effort and of expenditure on machinery, to "ensure" good quality. Neither the boasted improvements, the machinery, the experience, nor the European intelligence have individually or collectively improved the quality so far. As a matter of fact the quality has actually deteriorated. Coming upon the top of the present depression in trade and the low prices ruling this startling revelation is attracting the lively attention both of proprietors and shareholders on this side, and of dealers and brokers, and of makers of tea machinery. Where is the blame to be laid? is, of course, the natural outcome. Somebody or something, or a series of things must be the cause of the acknowledged deterioration. One blames the machinery and another defends his machine, but blames the abuse of his machine in incompetent hands. Another, or rather many, blame the "withering," as at present practised, and allege that a return to "panning" is the only course left. Others blame the excessive heat employed in dryers, and others the misuse of the process so-called "fermentation." Others blame over-plucking and the over-maturing of leaf before plucking, and others the exhaustion of soil from year to year, and the non-employment of suitable manures. Others think that the bushes are weakened by improper pruning, and that drainage is not paid sufficient attention to. Excessive abstraction of juice in rolling is also mentioned amongst other causes which it would serve no purpose to add to the sufficient list already given.

Looking at the above state of affairs from a broad point of view, what is most apparent on the first glance? We have an effect only too apparent—deterioration. We have, for this effect, a great variety of "causes" alleged, some of which actually clash with one another, and upon which there is most certainly no common accord even among the "experts" of today. * * *

Science hitherto in connection with the manufacture of tea, has been merely dallied with, accepted in spasmodic efforts without any regard whatever to continuity or to its complete connection with the *raison d'être* of each separate process as related to the perfect whole. Here has been the prime cause of wasted effort in the past, and this is now recognizedby many at this stage of the enquiry.

Planters should no longer be blamed for the sins of the past, since the noopereception of this first great point has been practically universal. It follows, then, that success in manufacture has hitherto savoured too much of chance, has hinged too much on the happy discovery, by mere accident, of some particulary "good" method, as judged merely by the *bulk* of the outturn. For an industry of such importance as the Indian tea industry to be in such a humiliating position is not likely to be endured for any length of time once the true state of affairs becomes realized. Every industry has passed through its initial periods, and suffered more or less during these as tea has done. Rule of thumb in the end has had to give place to scientific principles. Sugar refining is an illustration. Every sugar refinery of any repute now has its laboratory, and its various operations are but links in a perfect chain of chemical processes, and this is the proper outcome of improvements, machinery, experience, and European intelligence, once these have been systematically and scientifically brought to bear upon an industry to raise it out of its transition period. This end must be aimed at in tea manufacture. It must not be forgotten that when, under the exigencies of having to turn out unwieldly quantities from single estates, we threw aside the Chinese methods of manufacture and launched out upon our new career, we threw aside the experience of many centuries. We had until then followed more or less, certain methods which experience had taught the Chinese were the best, without our really knowing, however, the scientific basis underlying each process. We adopted machinery and mechanical dryers, and changed the whole system of manufacture, and for a time have been elated at the boasted "progress." We experienced the great advantages of machinery, but we had not counted the cost, as in our sublime ignorance we did not reckon with deterioration, which we had carefully opened the door to without knowing how or in what direction. That door has to be closed. Do not suppose that I am blaming any machine, far from that. Machines are essential to our factories, *but* we must reorganize our system of manufacture to bring about the good results we obtained in the old "panning" and *chulah* days; and before we reorganize our system we have yet to discover the scientific *raison d'être* for every detail necessary to our end in view—the production of perfect tea. We want no more dallying with science, no more spasmodic efforts—we want a scientific reason for the faith that will be in us when we can say, We can make good tea in all weathers. This grand aim is the only one that will satisfy the natural requirements of the case now that these are being recognized in the proper quarters. Proprietors are sick of excuses anent bad weather. Shareholders are asking why bad weather for manufacture is allowed to affect quality in these scientific days? and there is more sense in this question than in many asked by their class. Provided the weather admits of properly matured leaf being gathered, that is as far as dependence upon the weather should be allowed to affect the question. After that, quality and weather should be divorced. With the introduction of ensilage and harvest-saving machinery this has been brought about in other crops, tea "manufacture" must be over-hauled in its turn, and rule-of-thumb replaced by due attention to rules formulated in strict accord with the series of chemical actions, mechanical actions, &c., involved in the production of good tea. Those have hitherto not been sufficiently exactly understood.

Taking this view of the case, what do planters know of the reasons of their various processes, and what do they know about the chemical cause of the effect they produce? They know nothing, though some hold opinions about "fermentation" which would be amusing to scientific men. Note how many planters have been taught to send the juice flying in the rolling process under the idea of increasing the strength of their teas! That is only one

instance of ignoraace producing the opposite to the desired result.

Planters have not been properly taught, and for the very good reason that there has been no one to teach them. "Planters" of the future will fiud that the tea-house work will be handed over to a new order of men, who will relieve them of that heavy load of anxiety; and the tea-house department will have all the importance it merits. But this is anticipating events a little too fast. Let us consider what is wanted in the first place to lead up to that rational and only efficient cure. * * *

First I start on the premises that the production of "perfect tea" is dependent upon all processes involved being links in a complete chain of processes, dictated by science with a view to one end, and thus producing, as a result, that state of leaf in which shall be found all the elements of good tea *to the full power obtainable from the plant, soil and climate of the locality.*

"Perfect" tea is perhaps too much to aim at all at once as it would possibly involve greater expense than the extra profit it produced if all the question of soil analyses, manure trials, &c., were compressed into the time needed for the other side of the question, viz., the discovery of the Science of Manufacture.

Resting content then with merely the tea house manipulation as concerned in the production of *good* tea, I would define this manipulation as dependent upon a scientifically arranged series of processes, whereby that state of leaf in which shall be found all the elements of good tea, to the full power obtainable from the green leaf *as brought to the tea house*, is produced. That is, provided the leaf be brought into the tea house in the proper state —as to age, &c.—for manufacture, the weather should be so compensated by scientific appliaaces, &c., as to have *no deleterious effect upon the leaf during process of manufacture.* * * *

We have then first of all to find out by analysis of the best teas of specified classes of plant, from the various districts, the exact proportions of every ingredient. This will give us the Scientific Standard to work up to in each district, and which will no doubt ultimately be improved upon. It will tell us what constitutes, scientifically speaking, good tea. As to this I need hardly repeat we are in a very unsatisfactory state of ignorance at present.

Next, by sending out chemists specially selected for the purpose to each important district, with all necessary appliances for fitting up special laboratories on well settled factories, we should institute a series of tests and analyses carried on daily during manufacture *at each stage* for at least two seasons. These gentlemen should keep proper meteorological records from observations taken at least four times in the 24 hours, and full comparative notes as to the effects of the rainfall, temperature, &c., &c., upon the leaf brought in, and upon the leaf under process of manufacture *at each stage.* To do this the comparison must be completed with daily analyses of the tea made, and notes upon the hydrometer-reading in the tea-house and all other points bearing on the conditions ruling. Theoretically doubtless chemists could formulate instructions upon the salient points to be kept in view in preparing tea, but where the weather plays such an important part as at present, I doubt whether experimental scientific investigation, such as I have briefly hinted at above, is not absolutely necessary. Again the thorough comprehension of the present mode of manufacture is necessary to the chemist before he can properly realize the present conditions and base his advice upon those—which is a very important point to be borne in mind as his advice should aim at utilizing as much as possible present appliances. Further, without local experience, how is he to discover where wastage occurs, at present, of such vital items as the volatile flavouring properties, or of the strength-giving tannic acid, and yet to the loss of this latter will in all probability be attributed the deterioration which of late years has been so noticeable. The chemists, eventually having satisfied themselves that they had mastered the scientific details of tea manufacture, should go into committee, and produce a Guide to Manufacture, explaining therein the cause for each process, and the effect to be produced, with such suggestions as to overcoming atmospheric disadvantages as may be proper. Once people know what has to be provided for or provided against, the necessary means will not be long wanting. The tea house men of the future would thus have the chance of learning their business and of advancing in their profession, being in possession of a reliable pointer indicating that road to improvement which is so exasperatingly closed to them at present. * * *—*Home and Colonial Mail.*

THE TAXES ON TEA IN CHINA.

We hear that the Chinese tea-dealers are much excited at the proposed increase of inland dues. Many of them believe that a Decree will soon be issued based upon the reports which the provincial authorities have been called upon to furnish, and that the duties on teas from the country districts will be largely augmented. Some of the dealers have, we understand, sent orders to their agents in the tea districts to suspend their operations until the intentions of the Pekin Government are known. As no scheme of taxation has yet been formed, it may be that no such formidable increase in the inland dues as even the least of those mentioned in the Memorial will be sanctioned. But the Chinese merchants are aware that their Government is much pushed for money, and is likely to be in a much worse financial plight before long, and they fear, and expect, that it will try to fill its coffers by taxing foreign trade in the only way open to it. They are probably right in this, though it is difficult to believe that such an enormous increase in the dues as either of the alternative suggestions will be approved by the provincial authorities, and without their approval we should not anticipate that any great change in the present scale of dues will be made. Viceroys and mandarins of position under them, will, we hope, perceive that if an increase of from twenty-five to forty per cent. is made on the dues on common and medium teas, foreigners will only buy of these what is absolutely necessary. And this would prevent the Government from receiving not only much of the benefit to the revenue anticipated from the suggestions in the memorial, but would seriously affect the Foreign Customs collections, diminish what would have been received had the present scale of internal traffic taxation been maintained, and leave a large part of the tea crop on the hands of the growers. Thus the revenue from tea on its way to the port of shipment would probably be less than it now is, while discontent, and perhaps disturbances, would be certain to arise among the country growers. The loss on revenue from not letting well alone, and the fear of outbreaks among the peasantry and the large number of those who as boatmen and others of a similar class depend for their livelihood on the transit of tea, will, we hope, have great weight with intelligent mandarins. Rioting, and the summary extinction of mandarins, by the people, are the most effectual modes of controlling the governing classes in the provinces, and officials endeavour to avoid measures likely to bring about such expressions of public opinion. Still, the financial exigencies of the State must be very pressing, and may override the prudence which would govern officials at another time, and they may conclude that the burden of increased dues will be borne altogether by the foreigner. The old notion that foreigners cannot do without the China trade generally and tea in particular is still commonly held among the natives, and the mandarins no doubt think that we will pay the increased cost of tea rather than go without it. That may occur, but only when the continuance of the war has forced shippers to buy, and a good deal will have happened before that. Even an addition to the cost of teas one-half of that which the least of the alternative suggestions would cause, would give such an impetus to cultivation in India and other places, as might ruin the trade in China teas, and would certainly eventually lower their price. Mandarins are not generally supposed to care much for the traders and poor people of their country, when their own interests or policy are concerned, but driving away trade, as a large increase of the imposts on it would do, even if it gave them temporary financial relief, would be suicidal, and such a measure would still further alienate foreign nations. We cannot suppose that the foreign Ministers at Pekin will not use their influence to the utmost to prevent any serious increase in

the internal taxation on tea, and the impolicy of the proposals in the memorial is so obvious that their representations ought to be successful. The suggestions as to issuing opium warrants are too vague to allow us to estimate what the effect of them would be on the foreign drug. But as they will increase the cost of it to consumers the trade will probably suffer to some extent. The interests of the Indian Government are, however, so involved with opium, that the British Minisert is sure to be promptly instructed from home on all poitsn concerning the article.—*North-China Herald.*

CACAO FLOURISHING IN THE MATALE DISTRICT.

MATALE, 4th April.

I have seen nothing like the soil of this valley for richness and depth, except in volcanic Java. I had no conception previously of the luxuriant growth and bearing powers of cacao, which is the more remarkable in the face of the two successive years of drought during the north-east monsoon. There is scarcely any trace of blight. From Wariapolla, fifteen miles north of Kandy, where there are grand plantations, as also at Kowdapoelella, to the young plantation on the side of Arunagalla to the thirty-third mile, is eminently suitable for cacao. Experiments in tea have been very successful, while there is much coffee still looking well. A very promising experiment in aericulture is being made at Kowdapoelella.—ED.

TEA AND COFFEE IN DIKOYA.

DIKOYA, April 4th.

After last night's rain at Matale it is hot and steaming this morning and the sun is scarcely able to penetrate the shroud of mist. The contrast as I ascended was very marked: it was cool, with a breezie betokening rain. The process of the supercession of coffee by tea is visible up to Hatton, but the view into the extensive and beautiful Dikoya valley revealed expanses of fine well-cultivated coffee in which evidently faith is still retained. There is a fair sprinkling of crop but further blossom is required to set in order to make an appreciable crop.

TERRIFIC HAIL-STORM AT DIKOYA.

HATTON, April 4th.

There was a fearful hail-storm at Norwood in Dikoya on March 31st doing considerable damage to coffee and cinchonas. When the storm ceased there were three inches of hail stones on the ground. Thunder-storm and rain over Matale Valley on April 2nd.

PROSPECTS OF TEA IN DARJEELING AND THE DOOARS FOR 1885.

To the Editor "Indian Agriculturist."

SIR—The past month has seen the close of pruning. Managers are now, during their leisure time, repairing coolie lines making mats, *chalnies, tookries etc*; for the coming season. Labour is plentiful. Want of rain is telling on the young plants in the light-soil lands, and in some spots the old plants look sickly. It is not expected that we shall have an early season, unless we have rain during the next fortnight. Estimates on old gardens are not in excess of last year, as it is found there is a slight deterioration on old plants year by year, necessitating the cutting down of old bushes, or heavy manuring; the latter process, unless some new and cheap remedy is found, is not profitable. There is no doubt the soil is becoming poorer year by year. Hence it is believed that this is the cause of our teas not being so good as the were in days gone by. If planters would utilize their women and boys in carrying fresh soil and manure on parts of their gardens year by year in the winter season, or dig up the level gardens and mix this soil with a certain amount of chemical manure, there is little doubt that they would get a larger out-turn, and increase the quality of the tea at but a small expenditure. The pests—red spider, moth, green fly, and mosquito blight—are much dreaded by planters, and many an estimate and planter's reputation have been ruined by them. A remedy in the way of an insect poison, that has neither taste nor smell, was successfully used last year by a person in the Darjeeling district, and we believe the remedy can be obtained in the shape of a powder in tins, at the "Indian Supply Association," 10, Dalhousie-square. This remedy, we hear, is not a total cure, but checks the pests, and diminishes the ravages of the mosquitos and greenies to a point which is nominal. We read Mr. Cruikshank's speech of last week in the newspapers; and we think that the tea-agents should set the good example by reducing their commission by at least 1½ per cent; this would help the gardens considerably. There is an old saying—starve a horse and he won't gallop. This we might apply to coolies; if they are well fed they can work well—but if fed and paid badly, they will not do much work. It is better to pay a trained and acclimatized coolie a small bonus, than to get up a raw man from his own country. The supernumeraries attached to a garden are often useless. This should be looked to. Managers are often insufficiently paid. They risk a great deal in a bad climate, and it is a very are thing to ever hear of a planter retiring. Many go *home*, and many go home to die. Did any one ever see a tea planter who has lived in the plains all his life 50 years old? It is proposed at home to increase the duty on tea. If they do, we shall be the people to suffer. If England wants the support of her colonies, she must put a duty of I shilling per lb. on China tea. India can give England enough tea for all her wants, provided the duty is not raised.

R. RECNEPS.

March.

AGRICULTURE AND ARTS ASSOCIATION OF ONTARIO.—We have received a diploma from this Association for a collection of Books on the various Products of Ceylon. A diploma has been awarded to Mr. David Dawapurarathna for a plumbago elephant.

SHOWERS IN TOBAGO.—Welcome showers have had a most beneficial effect on the country, which was beginning to feel severely the effects of the recent drought. Though too late to be of much benefit to the coming crop, the general cooling down of the temperature made a very agreeable change from the dry hot weather they have so long had.—*Colonies and India.*

THE LANTANA PLANT.—Lantana called the planter's curse in Coorg, does not appear to be so black as it is painted. It is remarked of this plant that its growth in Coorg is very vigorous, and the spread of lantana in the Attur Forest close to Fraserpett is said to be truly wonderful, and may be expected in time to improve the character of this forest; while in and about Mercara the growth of young forest trees under the shelter of the lantana is most marked. At present, therefore, the spread of the lantana has its value by making the forest impenetrable, and leads to the hope that it may enrich the soil of abandoned estates which may be overgrown with it.—*Pioneer.*

TRIPARTITE FRUIT.—Extract from "Egypt and Mehammed Ali," by James Augustus St. John, 1834, Vol. II, p. 363.—An extraordinary fruit tree, produced by an extremely ingenious process. They take three seeds—the citron, the orange, and the lemon—and carefully removing the external coating from *both* sides of *one* of them, and from *one* side of the *two* others, place the former between the latter, and binding the three together with fine grass, place them in the earth. From this mixed seed springs a tree, the fruit of which exhibits three distinct species included within one rind, the division being perfectly visible externally, and the flavour of each compartment as different as if it had grown on a separate tree. This curious method of producing a tripartite fruit has been introduced by Boghos Youssouff from Smyrna, his native city, where it is said to have been practised from time immemorial.

THE AGRICULTURE AND ARTS ASSOCIATION OF ONTARIO have awarded Messrs. J. P. William & Bros. a diploma for their seeds, spices, etc., exhibited at the exposition at Toronto through Mr. E. R. Stimson.

THE *T. A.*—"The Superintendent of an Estate on which many experiments are tried" writes to support the opinion that absent proprietors or their agents would do well to supply as part of the office furnishing on each plantation, a complete set of the *Tropical Agriculturist* for ready reference on every possible topic connected with estate management.

TEA DRIERS.—At a time when special attention is likely to be given to this subject through the presence of Mr. Jackson in our midst, the experiments of Mr. C. A. Hay with Siroccos reported elsewhere will be carefully considered. At present, Ceylon planters on the whole favour such driers rather than those that make a demand on motive power to drive a fan or otherwise distribute heat. The greater cheapness of Siroccos is also in their favour. "First cost" is a great bugbear with the struggling Ceylon planter, even though terms are made easy by the scheme for "deferred payments" adopted by local firms.

COFFEE LEAF FUNGUS.—Udapussellawa, 23rd March. —There are indications of the approach of the little monsoon early. The seasons are keeping up their character of being out of joint. I am going to send to Marshall Ward a few specimens of leaf-disease. I should like to hear from him, how the *H. V.* looks now, both inside the leaf and out. I believe the microscope will reveal great changes and that Marshall Ward will scarcely recognize the old friend he diagnosed so long and carefully. [Our correspondent's observation goes to show that a great change has come over the coffee-leaf-fungus: it is no longer healthy.—ED.] Let us hope that in time we will have healthy coffee as well as luxuriant fields of tea.

PANWILA AND WATTEGAMA, 24th March.—We had some good heavy rain which has brought out and is still bringing out more blossom on all good cultivated coffee; it will also help on our tea and cacao plants which have stood the dry weather very well, and will soon bring out a blossom on our large cacao. We have a splendid climate for and have no wind to injure tea or cacao. Tea has been proved at three years old to give over the 400 pounds made tea per acre, and is of good strength. We have also some fine cinchona in our district, especially on Raxawa estate near 13th milepost: there was a time when some critics thought this estate would not grow cinchona: let them now come and see what a stitch in time has done—they will have to go far before they find finer cinchona.

GAS TAR AS A PRESERVATIVE OF HEALTH.—The serious outbreak of cholera with which France has recently been visited has caused inquiry to be made as to the extent to which persons engaged in particular manufactuing operations enjoy immunity from or are rendered more susceptible to the attacks of epidemic disease. It has been known almost ever since the establishment of gasworks that the exhalations arising in the various processes of gas manufacture—although, perhaps, not specially pleasing to the olfactory organs—are not detrimental to health, but on the contrary, highly beneficial in special forms of disease, such as whooping cough, and croup. Inquiries were made chiefly in connection with the employés of the Paris Gas Company. Dr. Lemaire found that those whose duties did not necessitate a prolonged stay in the parts of the works where tar was to be found were liable to all kinds of ailments, and formed a considerable proportion of the number on the sick list; while among the workmen specially occupied with tar, only three were sick in the course of seven years. This result is all the more striking when the number of workmen in the service of the company at the period referred to is considered. There were altogether 20,553 men, of whom 764 were engaged in some occupation connected with tar.—*European Mail.*

THE *T. A.*—I consider the *T. A.* an admirable *digest* of all matters in which one is interested, and invaluable as a volume of reference.—*Uva Planter.*

PLANTATIONS IN THE NORTHERN TERRITORY.—At length a new spirit seems to have been infused into the long languishing plantation industry in the Northern Territory. A new Company, with Mr. W. B. Wilkinson as Secretary, has been floated, under the name of the Daly River Plantation Company, with a capital of £10,000 in £1 shares, to take over the concession of 10,000 acres of land on the Daly River promised by the Government to the old Delissa Company. The first meeting was held on Friday, and the Company was then fairly inaugurated. On Monday the new Company's tender of £600 was accepted for the valuable plant and machinery of the Delissa Company—a great acquisition at an absurdly small cost. The new Company are now advertising for a Manager, and they intend to go to work in a thoroughly practical way. The plant purchased is considered to be one of the most complete in the colonies.—*South Australian Register.*

MR. JOHN HUGHES ON THE CEYLON TEA INDUSTRY. —Writing to us under date the 6th March inst., Mr. Hughes says:—"It seems from the letters in the *Observer* that there is a danger of planters going in for *quantity* instead of *quality*. This would be a great mistake, for Ceylon tea has acquired a name for *quality*, giving a rich dark-coloured liquor, good flavour, but not so strong as *Assam* tea, there being really less tannin present in the former than in the latter. It would be great mistake to flood the market with a large production of coarse leaf. My friend and namesake (Mr. George Hughes) recently read a short notice on the formation of phosphate of lime in the West Indies. I enclose abstract of paper in case you should like to make use of it. I will send you papers which appear likely to be useful for the *T. A.* I have frequently mentioned the *T. A.* to my friends interested in planted tea, coffee, &c., and shall continue to do so. I will see what I can do in the way of an article about *tea manures* shortly; in which I shall specially point out the ingredients carried off the land by an average yield." Mr. George Hughes's interesting paper will appear in our *Tropical Agriculturist.*

THE TREATMENT OF COOLIES.—Referring to this subject, a Jamaica paper says:—"Prejudiced critics forget, or rather do not wish to remember, that the coolie immigrants in the West Indies are protected—as the labourers of no other class in the world are protected —against aught that savours of injustice, bad faith, or oppression. In Trinidad, Jamaica, British Guiana, and every other Colony having indentured coolies, staffs of immigration agents or protectors are employed, whose duty it is to see that the terms of the contract are fairly and fully carried out; so that it is absolutely impossible for overtasking or any form of oppression —such as the *Times* has the audacity to allege—to exist in Trinidad or any of the other coolie-importing Colonies. The law which we may term the Coolie Labour Contract provides the indentured labourers with a hedge of safeguards which the most evil-disposed planter would not dare to break—and against which there would beat in vain even the full tide of the British capitalist's rapacity and violence. We know that the *Times* and its congénial plantophobes affect to look upon immigration as another form of slavery. Well would it be for the agricultural labourers of Great Britain and Ireland if they could exchange places with their Oriental confrères, who in the course of five or ten years effect savings sufficient in many cases to support them all the rest of their life, and save them from anything resembling the cruel Bumbledon and coarse demoralization of the English workhouse.'—*Colonies and India.*

TEA CHESTS.—Mr. C. W. Horsfall sends us a sample of one of the half-chests as advertised in the *Observer*. It is, he says, not specially selected but is a fair average sample made of hal wood, size 18 × 16 × 15 outside, *i.e.*, equivalent to *exactly* 2·50 cubic feet, or 20 to the shipping ton. Each shook is numbered, and every piece of wood marked for subsequent identification if necessary. This sample can be seen at our office.

PROGRESS IN JOHORE.—On the 5th March, Mr. Tan Hai Seng entertained H. H. the Maharajah and a large party of Government Officials at luncheon at his estate at Passir Gudang, whither the guests were conveyed by the "Pulai." The entertainment was enlivened by a "Pek Jee" wayang (*i.e.*, a wayang performed by children), and afterwards a Malay boat-race afforded amusement to the guests, who returned to Johore in the evening. Liberian coffee and a little cacao are planted on the estate, both looking very healthy, particularly the former, of which some 50 acres are nearly in bearing. The cacao plants are entirely in the open, and one is afraid to say what will become of them unless shade trees are at once planted. On Monday night, the Maharajah started for a trip to Bandar Maharanee in the "Pantie," arriving there on Tuesday morning. The afternoon of that day was spent inspecting the newly built houses and the new roads. On the following morning, H. H. accompanied by the Datu Bintara Luar and other officers visited the Kesang district, *via* the Kwala Kesang police station, and spected a road in course of construction, which starts from a little way above the station, running in a north-west direction to meet a bend of the Kesang river. At the distance of about a mile it will turn at right angles, so as to come out at another bend of the river opposite the Malacca Government police station. The road is being made by a contractor, and will soon be completed. A large number of Malays, Chinese, and Javanese squatters have already taken up lands alongside this new road, attracted by the fertility of the soil and the easy terms of tenure. To all appearances, the district, with a sufficient number of roads, is destined to become what Padang is now, namely, a rich coconut and betel-nut producing country.—*Singapore Free Press.*

NORTHERN AUSTRALIAN TERRITORY: TOBACCO.—We have received from Mr. Bath, Secretary to the Minister of Justice, a sample of tobacco manufacture in Adelaide from leaf sent from Palmerston. This tobacco is in every way a great improvement upon that made roughly in the Territory and submitted to us some months ago. The leaf, when received, was forwarded to Messrs Dungey, Ralph, and Co., of Adelaide, and made up by them, and this report of theirs upon it—a report which seems fully justified by the sample and the facts—will be read with interest and gratification:—"Herewith we send you sample of twist tobacco manufactured from leaf grown in Northern Territory, and sent to us by the Hon. the Treasurer for report. These samples were treated in exactly the same form as we treat ordinary American leaf. The sample of leaf submitted very much resembles the heavy Western (American) tobacco, which is so profitably grown in the States, only that the Western or Kentucky and all other dark tobaccos are all thoroughly sweated and cured ready for the manufacturer, whereas this tobacco is simply sun dried, and therefore has no keeping qualities. A thick, fleshy leaf, with heavy stem (fully 30 per cent. waste in this respect), burns free, with fairly white ash, and could be used with American tobacco, one third of Northern Territory to two-thirds American; and if the portion we operated upon is a fair sample of the bulk, we should have no hesitation in working it in these proportions. We are of opinion that if the tobacco is grown further inland it will be much richer in nicotine, and with ordinary care bestowed, on it, and a thorough knowledge of the weating or curing, and packing proceeses, in a short time sit would compete successfully against American growths of twist and plug tobacco."—*South Australian Register.*

THE GRAIN COMMISSION IN BATTICALOA, CEYLON.—We would call attention to the letter on this subject on page 820. The writer evidently gives all that can be said *on one side*, but nothing of the other side of the case. The reference to the railway is scarcely fair, for we would inform "Fiat Justitia" that the cost of the Railway Department and every cent of outlay is debited to the railway, and yet for years it paid 10 to 12 per cent. As to Commutation, in most districts Government have lost revenue by it, the rates fixed being lower than the average of rents. If the case is otherwise in the east of the island, we should like to see the Commissioner's views.

AN ENEMY OF THE CACAO TREE.—On the 10th of March Messrs. J. P. William & Bros. of Henaratgoda wrote to us:—

"By this post you will receive a tin box containing a bottle with a kind of cricket caught last evening about 7 p.m. from one of our cacao trees. First the cricket begins to eat the stems of the young cacao pods, and after stems of all, small and large pods all over the tree; consequently the pods begin to drop. Though we have watched several days the cricket was not to be seen, so we have covered all the stems of the pods with clay in the daytime yesterday, and at the time of catching it we found that the cricket is eating the bark of the tree; previous to this the bark was not touched. We shall be glad to see your remarks on the matter and shall be obliged by your handing over the cricket to the Government Museum."

We sent the insect to our entomological referee, who wrote on 24th March:—

"The insect sent to you by Messrs. William & Brothers is a locust, an immature female. It belongs, as far as I can make out, to the family *Gryllidæ*, but I am unable to determine its species. I have watched its habits in confinement since I have received it a fortnight ago, as I have been able to supply it with small branches of a cacao tree growing in our garden. It is a night-feeder, and during the daytime it clings closely to the branch with its middle pair of legs held closely to its sides, the feet clasping the branch. The hind legs are streched out to their full length in a straight line, the feet together, holding on to the bark. The front pair of legs are also stretched out in the same way and kept in a line with the antennæ, which are long. In this position the insect appears pointed at both ends, and being of a dull brown color, and having a rough exterior, it easily escapes detection, appearing at first sight like an excrescence, such as is often seen on the branches of trees. It is in fact a fair example of insect mimicry. The specimen under observation measures, when lying in repose, a little over two inches. It is a voracious feeder and completely strips the bark off the branch upon which it may be feeding. I placed some coffee branches against the cacao branches, but it has not touched them, preferring, when pressed by hunger, to eat the cacao leaves. It is probably an insect not likely to be found in any great abundance, and therefore the mischief it does may not be very serious."

Before we had time to insert the above, our referee wrote to ask us to delay insertion, as the insect was undergoing a change. He now writes:—

"Since the above was penned, the insect has assumed its perfect state. It has not altered much in appearance, except that it has had two pairs of long wings, which extend much beyond the point of its abdomen. Its color is the same, and it would be quite as difficult of detection on a cacao tree, as in its undeveloped state. I happened to be up very early one morning, about 1 o'clock, and then noticed it had just cast its skin. The empty skin was quite complete and hanging on to a twig close to its late possessor. An hour or two later, I discovered that the discarded skin had been completely devoured by the insect, and not a vestige of it could be seen except by the aid of a microscope. The ercature must have followed an instinct which prompts it to obliterate all traces of so conspicuous an indication of its close vicinity. It still feeds at night on cacao branches, and remains motionless during the daytime. There are a few specimens of the insect in the Colombo Museum, which are labelled *Cynatemera.*"

A Mustard Plaster.—In making a mustard plaster, no water whatever should be used, but the mustard mixed with the white of an egg; the result will be a plaster which will "draw" perfectly, but will not produce a blister even upon the skin of an infant, no matter how long it is allowed to remain upon the part.—*Farm & Fireside*, 1st Feb.

Vanilla.—We are at length able to announce a sale of Vanilla in our market. It was not a very important lot, but the high rate of exchange has allowed the article to go off at relatively high price. A lot of 137 kilos of 6 inches and upwards realized R18 per kilo; a lot 10 kilos of fine frosted vanilla R20, 20 per kilo; a lot of sorts and split obtained 8·00 per kilo. These were the only sales during the month—there are a still a few small lots which will doubtless be offered for sale in the course of the month on account of the prices realized.

Improvement of the Prickly-Pear.—Mr. W. Wilson, Director of Revenue Settlement and Agriculture, wrote to the Secretary to Government Revenue Department, under date Madras, 19th February 1885, submitting a file of correspondence that had passed between his office and certain gentlemen regarding the suggestion made for the conversion of the prickly-pear of Southern India from a noxious weed into a wholesome fruit-bearer by grafting on it the edible cacti of Southern Europe in a letter addressed to this Government by Dr. Bonavia, Civil Surgeon of Etawah, North-Western Provinces. The opinions (said Mr. Wilson) are diverse, but lean on the whole to the desirability of introducing here the best varieties of the edible cacti of Southern Europe. The general opinion is that if the planets will grow here they will thrive on their own roots, and that it would therefore be necessary to graft them on the common prickly-pear at all. That one variety at least of the edible cacti of Southern Europe will thrive in this Presidency will appear from the letters of Mr. J. F. Price, C.S., and Dr. Shortt. The former gentleman has seen it near Karunguli in the Chingleput district and also in parts of Salem. From what he says of the specimens he saw, however, it would seem that the plants were in a degenerate condition. Dr. Shortt writes that the thornless cactus—Nopaul or *Opontia Cochinellefera*—which is the variety cultivated in the gardens at Malta, is already thoroughly acclimatized in Southern India, and is now growing in his own garden at Yercaud on its own roots; while strongly advocating its cultivation both as a fruit-bearer and as a fodder for cattle, he thinks it necessary for these reasons to import or to graft it. The Agricultural Reporter to Government and Mr. H. S. Thomas, C.S., both deprecate its introduction; the former does not think the experiment worth trying because it is more desirable to remove the prickly-pear on which it is proposed to graft the edible cacti than to retain it. Mr. Thomas fears that, if introduced, it would only increase the present evil of prickly-pear, as the seeds passed by men and the lower animals would probably result in a growth of wild cactus which would be all the more extensive, the more popular the fruit became. Mr. Price thinks the experiment worth trying, but does not think that the introduction of the edible cactus would lead to the uprooting of prickly-pear, nor does he think that it would be necessary to graft the plants on prickly-pear. Colonel H. McLeod, R.A., and Professor M. A. Lawson both warmly approve Dr. Bonavia's suggestion, and Colonel McLeod who knows the edible cacti in their own country, and says that their fruit forms a great part of the sustenance of the native population there while they are in season, has very courteously addressed the Governor of Malta and the Commissioner of Larcana in view to the supply to this department of specimens of the best fruited varieties to be found in Malta and Cyprus. The results of the experiments made with these, when they are received will be reported in due course. The Government order on the above, was as follows:—The Government will wait the results of the experiments which should be made with the plants expected from Malta and Cyprus. Mr. Wilson, who should consult Mr. Lawson upon the matter, should see that those plants are put down in suitable localities where the climate is sufficiently dry. Colonel McLeod will be thanked for the trouble he has taken in the matter.

An Increased Export Duty on China Tea is very probable in view of the warlike expenses of the Government; but the fact is that between the internal levy (see Mr. Colquhoun's book) and the seagoing duty, the tax at present is nearer 2¾d than 1½d per lb. So that the Chinese have not much margin unless they would suppress the trade in their common teas altogether.

Indian Labour in South Africa.—Whatever may be said or thought now, a quarter of a century later, it is beyond dispute, that in 1858 and 1859, all the hopes of enterprize and of progress in this colony were held to depend upon the introduction of the indentured labourers from India. That the progress of the colony has been quickened and its wealth enhanced by the labours of the Indian no one can, we imagine, deny. The evils that are complained of with so much justice have nothing to do with the work of the coolie on the estates where he is employed. They were evils never foreseen on his arrival. They have been evolved by circumstances unrecked of at that time. All that the advocates of Indian immigration hoped for and fought for in the first instance was that the cultivation of the soil should not be impeded or prevented by the want of labour. The native population had utterly failed to afford relief, and if the resources of the country were to be turned to account, labour must be sought from some external source. To blame anyone for the contingent ulterior effects of coolie immgration in the shape of permanent colonization and commercial rivalry is as rational as it would be to blame the inventors of the steam engine for having ousted handicraftism pure and simple. It will be well when dealing with this question, as it must soon be dealt with, to bear this in mind. The question before the country now is, not how best Indian immigration can be stimulated and conserved—it needs no stimulation—but how best the evils to which it has given rise can be controlled and rectified.—*Natal Mercury*.

The Properties of Rhea Fibre are wellknown, and machinery has now fairly overcome the difficulty of its preparation. There are, however, certain objections to rhea which are likely to prevent the fibre proper from ever taking a position among textiles much higher than it at present occupies. It is too good, too strong, too valuable for ordinary purposes. A lady would have to live 100 years before she could ever hope to wear a hole in a rhea-fibre dress. It absorbs too much dye, it is too hard, it creases so badly as to appear shabby the first day it is worn. But for many minor purposes rhea will always be in demand. It is therefore unfortunate as well as amusing to find that, with all our fancied knowledge on the subject, the plant itself is still a standing mystery. In 1875 Dr. Forbes Watson wrote the first reliable account of the fibre. He gave three plates of rhea or rhea allied plants. One was rhea proper, another the poi-rhea of Assam, and the third the Nilghiri nettle plant. Unfortunately in giving a drawing of the last named plant, he gave, by mistake, *Girardinia eylanica* under the name of *G. heterophylla*, and his account of the plant illustrated actually related to the fibre of *G. palmata*. Thus three plants were hopelessly confused; and an error of this kind dies hard. In the *American Agriculturist* (January 1885), Dr. Forbes Watson's plate of the poi-fibre plant (*Maoutia Poya*) is made to do duty as an illustration of the true rhea (*Bœhmeria nivea*), and is introduced in the course of a lamentation over the depravity of botanical science. In Baillon's "Natural History of Plants" an engraving is given of what is called rhea (*B. nivea*), in which the plant is shown to have opposite instead of alternate leaves. One might multiply such evidences of carelessness, but enough has been said to show how this valuable fibre has suffered from want of accurate investigation. There are some 18 species of *Bœhmeria* in India, and, including all the allied non-stinging nettles, there are no fewer than 45 plants so closely allied to rhea proper that they have been all mistaken for the true rhea fibre plant. Including the stinging nettles, there are 70 or 80 fibre yielding plants which, with the exception of four or five, have never been examined by Europeans, although they all yield fibres used by the natives, and are practically cousins of rhea fibre. When may we expect to have the properties of each of these 70 or 80 rhea-like fibres made known?—Calcutta *Englishman*.

Correspondence.

To the Editor of the "Ceylon Observer."

ARECANUT CULTIVATION IN CEYLON.

March 24th, 1885.

SIR,—In reviewing a letter from Mr. Borron on page 791, on arecanut cultivation, you draw comparison between his figures generally and the statistics of a "Planter from the South"—vide *Tropical Agriculturist* (and might also have added a little work lately reviewed by Messrs. Cave & Co., from which they gave a greater portion of the article in it ou Arecanuts)—with the remark that "we need hardly say that Mr. Borron's calculation seems the safe practical one." The only inference to be drawn is that you consider a "safe" estimate synonymous with a "practical" one, or that you wish it to be understoood that my figures, as the writer of the letter referred back to, are not so—in other words that they are misleading. An inference in justice to myself, but more particularly so for the reputation of a promising industry that I look forward to will work substantial benefits for the island and many in it, you will allow me to question. Mr. Borron has given information all interested must feel obliged to him for, and whilst wishing him their full gain, as a matter of public benefit, I hope his letter may be the means of eliciting from the correspondents the remaining secrets of the industry he does not see it wisdom to dispense gratuitously. Further he may be, I ought to say must be, as speaking from personal experience, quite right that the conditions obtaining in Matale East are not favorable to a greater number nf trees to the acre than 480. I would though venture to doubt the relevancy of his parallel between the coconut and areca, save that they are both palms; in fact quite prepared to prove the extent of their dissimilarity of habit, by groves of as healthy and heavy bearing trees in this neighbourhood as he could wish to see (at an estimated yield of 300!) growing as thick as they can well be crowded together.

All I will now say further is, that, taking my experience from this district, from characteristics of soil and climate, I should regard as a suitable one (though irrigated, the palm, I believe, grows and fruits well even in the Eastern Province!) I see no reason, with all deference to more weighty knowledge, to alter my figures or opinion in any respect, —that it is but a reflex of my neighbours' independent deductions and practice, and that, though optimist views are to be deprecated equally as much mischief as can be done, and as in detraction to a new enterprize, extension stayed by understating its fair capabilities. Few men with the prospect of six years to wait would be tempted by the hope of nett returns not to exceed as I gather, £4 per acre, and the prospects of half this going by theft; whereas my figures, if fair ones as I believe them to be, point to profits that, though at this, will pass muster.

With reference to suitable localities the question is: Am I right, or Mr. Borron?

PLANTER FROM THE SOUTH.

TEA DRYING: CAREFUL EXPERIMENT WITH SIROCCOS.

Blackwater, Nawalapitiya, 26th March 1885.

DEAR SIR,—Allow me to send you the result of two careful trials with two No. 1 Siroccos, one of which has the old kind of air-heaters and the other the newest. I was most particular in the weighment of fermented leaf, in the taking out of trays when dry, and in noting the time. You will see the No. 710 only gives me 30¾ lb. with 10 trays and the No. 737 with 9 trays 33 lb., making a great difference between the quantities got by Mr. Armstrong, viz., 46 and 48 lb.

I do not merely state that I worked my Siroccos with the thermometer at 275, because for one hour that exact heat could not be kept, so I show the rise and fall.

My machines stand in one large pit 18′ × 10″ × 4′ 6″ and have splendid draught, the mean temperatures o the two machines being 280 and 278 are higher than Mr. Armstrong's; yet the results are far from being as good. I should like very much to know, 1st, were all four trays put in at commencement? 2nd, were the bottom trays turned over and respread?

I know that there is a great difference in the working of Siroccos, some working better in pits and others on the level; still 33 against 48 is very great.—Yours truly,

C. A. HAY.

A No. 1 "Sirocco."
No. 710 Old style of air-heater.

No. of Trays.	Put in Sirocco.	Taken out of Sirocco.	Time Taken.	Time.	Therm
1	11-17	11-31	14 min.	11-17	275
2	11-17	11-37	20 ,,	11-27	280
3	11-17	11-43½	26½ ,,	11-30	282½
4	11-17	11-49½	32½ ,,	11-33	285
5	11-32	11-53½	21½ ,,	11-40	280
6	11-37½	11-59	21½ ,,	11-52	282½
7	11-44	12- 4	20 ,,	11-58	275
8	11-54	12-10	16 ,,	12-6	280
9	12-	12-15	15 ,,	12-9	282½
10	12-01	12-20	16 ,,	12-17	285

From putting in 1st tray at 11-17 until the taking out of the 10th at 12-20, 1 hour and 3 minutes, I only got 30¾ lb. dried tea. Every tray had exactly 9 lb. weighed leaf put on, and every bottom tray was overturned and re-spread taking about ½ minute in the operation; no tray was left in one second longer than necessary to quite dry the biggest leaves. I have never used my Sirocco so low as 275 before, generally working at 300 and 310; still there is a great difference between 30¾ and the 48 Mr. Armstrong obtained.

A No. 1 "Sirocco."
No. 737 Newest style of air-heater.

No. of Trays.	Put in Sirocco.	Taken out of Sirocco.	Time Taken.	Time.	Therm.
1	7	7-16½	16½	7	275
2	7	7-21¼	21½	7 5	280
3	7	7-28	28	7-10	286
4	7	7-31	34	7-20	275
5	7-17	7-40	23	7-25	280
6	7-21½	7-45½	23¾	7-35	286
7	7-28½	7-51	23½	7 40	277
8	7-34½	7-56½	22	7-50	275
9	7-40½	8-5	24½	6	272

From putting in the 1st four trays at 7 a.m. until the 9th tray was taken out at 8-05, 1 hour and 5 minutes, I only got 33 lb. dried tea. Every tray was spread with 9 lb. fermented leaf. The time taken in pulling out bottom tray, shifting down the other three and putting in the fresh one on top occupied from 20 to 25 seconds; once re-spreading bottom tray, 40 to 45 seconds. The last tray of all was not re-spread, and just took 4 minutes more than all the other bottom ones. Time deducted from hour in re-spreading 8 trays, 4 minutes. Time taken in shifting trays, 3 minutes.

THE PROGRESS OF CHENA (FOREST) DESTRUCTION IN CEYLON.

29th March 1885.

DEAR SIR,—In 1879 a block of 40 acres of jungle in the lowcountry was applied for, for the purpose of trying Liberian coffee and cocao. The application was an urgent one and was backed up by the Assistant Government Agent and the Government Agent of the Province, but nevertheless the land was not surveyed till late in 1883 and has not been put up for sale yet. The applicant from a reverse of fortune is not now in a position to buy the land, but even if he were he would not take it for R10, as all the jungle on it has just been felled by natives for chena cultivation. This is only one of many cases of a similar nature and instances the loss Government sustains from its apathy in carrying out the provisions of its laws, and doing its work.

Two years ago the district favored with the situation of this land boasted of over two hundred and fifty convictions a year for chena clearing, but

now twice that number wod punnish one-half of the offenders; and why! because it was then the duty of a particular officer to carry out the work, and is now the duty of everybody—or actually nobody—to do so.—Yours faithfully,

W. S. FRASER.

NEW PRODUCTS: BARK OF *ALSTONIA SCHOLARIS.*

DEAR SIR,—I have pleasure in sending you London report on the bark of the *Alstonia scholaris*. With cinchona bark at fivepence a unit, it is at present hardly worth attention, but, when the value rises again to about a shilling, then the Alstonia may become deserving of consideration.

Alstonia scholaris, called "rukattana" in Sinhalese, and "mohira vingai" in Tamil, is a very common jungle tree in Ceylon up to the elevation of about 3,000 feet.

The wood is bitter, white, close-grained, useful for boxes, etc.

The tree abounds in milk, which is very hurtful should it touch the human skin.

Alstonia constricta is an Australian member of the same family.

It is much to be regretted that the Government Medical Department does not test and report upon the many native drugs allowed to grow wild and waste in Ceylon, save their occasional secret use by the native wedarala, when compounding his mixtures. About two years ago I repectfully begged Dr. Vanderstraaten of the Government Civil Hospital to test a common vegetable drug used and recommended in India, and sending him a small quantity for the purpose, but I have never even received the courtesy of an acknowledgment.—Yours faithfully,

A. G. K. BORRON.

ALSTONIA BARK.

The specimen lately imported was the bark of *Alstonia scholaris*, the Devil Tree, a tree belonging to the natural order *Apocynaceæ*, and indigenous to India, tropical Africa, Siam and Eastern Australasia. It is highly esteemed by the Hindus as a tonic, antiperiodic and general febrifuge. In consequence of its undoubted value, it is official in the Indian Pharmacopœia. The chemistry of the bark has been exhaustively worked out by Jobst and Hesse, who isolated from it the alkaloid Ditain and, in a subsequent research, several other definite bodies. Recent therapeutic investigations conducted in America have proved that ditain in the same doses as quinine sulphate produces similar and equal physiological effects, but that the exhibition of large doses do not give rise to any such unpleasant after-symptoms as follow the administration of large quantities of the cinchona alkaloid.

The specific name *scholaris* is derived from a curious use to which the Hindus apply thin boards of the wood of this tree sprinkled with saud: they are used by the children to trace their figures and letters as we use slates.

There is, at present, little or no demand for it in England. *Alstonia constricta*, or *Queensland* fever bark, has been found to contain some important alkaloids, one of which—Alstonidine—is said by Dr. O. Hesse to combine properties similar to those of quinine and nux vomica: this opinion has been confirmed by Dr. Bixby, who met with considerable success with this drug in the treatment of cases of typhoid, synochal and puerperal fevers, coryza, &c.

GRAIN CULTIVATION IN EASTERN CEYLON.

SIR,—The Grain Commissioner, after working with his assessor and clerks for some time, has at last commenced to hold meetings. A few groups of villages have been finished, and he has declared the assessment to be about R2 per acre for annual commutation, and R2·50 for crop commutation. This, for two groups of villages where the crops are not in any way benefited by the irrigation works, is an assessment that takes all by surprise. The average price for the last fourteen years may be taken to be R1 per bushel in the town and 75 cents in the country. To bear an assessment of R1·75 or R2, the produce must be about 21 bushels per acre near the town, and about 28 bushels in the country. We are prepared to show satisfactorily that both the average yield and the price are set much higher than they should be.

1. That Batticaloa, with a coast line of more than a hundred and fifty miles, with a sparse population, with only one port, and that too closed for five months every year, has not abundant facilities for disposing of its surplus paddy, is well-known to all. The poor peasant proprietor and even the majority of the so-called well-to-do people, borrow the seed and consumption paddy, and are compelled to pay the usurious interest of 50 per cent for the same. The cultivator is therefore obliged to deliver his paddy to the man that advanced his capital at R5 per *avanam* of 7½ bushels in the suburbs and for much less in the interior, *i.e.*, at the rate of 50c to 75c per bushel, but the Government has been usually selling it to the renters at R1 per bushel, and, during the famines of 1878, 1879, and 1885, at much more than a rupee. During the last fourteen years Batticaloa has unfortunately been subject to four seasons of drought and scarcity. With starvation before them and the crops rotting in the fields, the cultivators or their creditors buy the tithe at any rate.

2. Assuming that the people must anyhow abide by the averages calculated by the Kachcheri records for the past 14, years, the Grain Commissioner must equally abide by the averages calculated from the same records as to the yield of paddy per acre. But this he rejects *in toto* and almost arbitrarily adds from 80 to 100 per cent to the average yield, the rumoured reason being that the former assessors and headmen must have been systematically underrating the yield. Though this may be true as to some fields, in all cases of estimates this cannot be correctly asserted of the whole of the district. The Commissioner estimates a yield of seven to eightfold per acre in unirrigated fields. The "Ceylon Directory" and Mr. Mosse estimate only a fourfold yield. The Paddy Tax Commission of 1867 would not go beyond fivefold, *i.e.* 12½ bushels to the acre. Nor can two crops be raised from the same land, as at Matara. In the irrigated portions of Batticaloa, or in the *best* of the unirrigated portions, a man with a pair of bulls is able to cultivate 6 acres of land, and the cost of production is the following:—

For Six Acres.	*Bushels.*		*Profit to Capitalist.*
(1) Seed paddy ...	15	+	7½
(2) Consumption paddy ...	15	+	3¾
(3) Ploughing expenses ...	7½	+	2½
			13¾
(4) Vaddai Vitan and Adikari by Government rule ...	1		
(5) Threshing buffalo ...	4		
(6) Bird boy ...	2½		
(7) Mamoty ...	1¼		
(8) Ploughshares ...	3¾		
(9) Additional men for reaping and stacking ...	7½		
(10) 3 do. for assisting in threshing ...	3		
(11) Carriage for 14 avanams *i.e.* at sevenfold yield ...	6¾		
	bus.		bus
	64½ + 13¾ = 78 ÷ 6 = 13		

The cost of production would be 13 bushels per acre, and to this must be added the bare expenses of the cultivator for about two months from the time of reaping to the harvest; his commutation tax R1·50 and his April new year paddy. For otherwise he would require 18¾ instead of 15 bushels for his consumption paddy, and for this addition of 3¾ bushels his creditor would charge 50 per cent interest. As the lesser of the two evils, the cultivator takes at least 4 bushels after the harvest or during the time, and this represents his sole gain for a year. Adding these *four* bushels, deferred wages of labor, to the 13 bushels, the entire cost of production is 17 bushels per acre including the profits of *capital* and the wages of labour

the balance, if any, is the rent of land. At the Commissioner's calculation of an eightfold yield $2\frac{1}{2} \times 8 = 20 - 17 = 3$. Three bushels represent the rent of land. When the Commissioner demands R1·50 he demands the whole of the rent to be paid to Government. When he demands R2 per acre he actually wants the landowner to pay up virtually the whole of the rent and something more.

In British Burma the yield is 42 bushels and the assessment R2·50 per acre. On this the *Indian Agriculturist* remarks :—"The State thus exacts a larger payment from the cultivator than the so-called rack rent levied by the zemindar in the Lower Provinces under the Permanent Statement." If the amount be a rack rent where the land yields 42 bushels per acre, what shall we say of the Batticaloa assessment? Let experienced Civil Servants answer. Sir B. Frere says :—"Instead of taking from the ryots not more than half of the net produce the assessments resolve into

(1) A *land tax* fixed more or less arbitrarily absorbing a varying proportion of the net produce;

(2) A *full rent* leaving nothing to the cultivator but the wages of his labor and the interest on his capital;

(3) A *full rent* and *something more*, sometimes trenching on the wages of labor and the profits of capital."

(4) Sir L. Mallet says :—"Sometimes even lands that pay no rent and do not pay even the cost of cultivation have been assessed."

(5) Sir W. Wedderburn says :—"Even lands not paying the cost of cultivation are assessed."

The Settlement Officers go by rule of guess.

Mr. Stormont of the Government farm in Kandeish says :—"Seven specimen plots gave an average crop value of £2 5s per acre according to Government, but the actual outturn gave only 19s 6d per acre!"

The first of the calculations for the production refers to the best classes of fields yielding an eightfold. But the average yield for Batticaloa North, we are positive, can never be above fivefold, *i.e.* 12½ bushels per acre. Deducting 2½ bushels seed paddy we have 10 bushels, and one bushel at R1 in the town and 50c to 75c in the country is what is legitimately due to Government. The cultivators have honestly paid for their irrigation works. There is no lack of industry in them. After paying up the tenth or the last instalment of the water-rate, they are told that a further, though lower, rate would be levied on them *perpetually*. They have to thank themselves that they got no inkling of this beforehand. The Queen's Advocate, when introducing the Grain Tax Ordinance of 1878, got his speech translated into all the vernaculars and circulated in pamphlet form. The Government profess their willingness even to give up a portion of their Land Revenue to better the condition of the cultivator.

Look at the results. Galle district, average grain revenue for 14 years, R34,108; fixed by the Commissioner now, R38,694 Hambantota district, average revenue for 14 years, R27,000; fixed by the Commissioner, R34,000. As for Batticaloa, the Commissioner predicted two years ago :—"On a revision of the paddy tithe, the produce will be nearer R80,000 than R60,000, in which case Government will realize 20 per cent per annum" on the outlay in the irrigation works. If the railways should pay 5 per cent, 3 per cent, 0 per cent, minus 2 per cent, why not be contented with the 13 or 14 per cent now paid by the poor cultivators of Batticaloa? The Government wishes to free them from the hands of the renters; why play them into the hands of usurers? Let the Commissioner of Batticaloa North select what, after inspection, he considers the *best*, the *middling* and the *worst* of the fields in any group of villages, and let him send his own assessor to supervise the harvesting of these fields and find out the average yield; the cultivators and landowners would give him every facility in this work. Now the peasants are simply called to be present and see their respective amounts registered. The poor people ask for no favor but a just assessment after a due enquiry and consideration. The Commissioner is not to be a paid Government advocate but to stand between the Government and the poor, as others are reported to have done in the colony 30 or 40 years age. Oh for the shades of the dead!

FIAT JUSTI TIA.

TEA MANUFACTURE is treated in a long and comprehensive paper by an old hand in the *Home and Colonial Mail*, from which we quote on page 813. The writer argues that the quality of Indian teas is decidedly falling off, and that science must be brought to bear both on the cultivation and preparation. Analytical Chemists are required in every tea district. The introduction quoted from today is rather theoretical; but, perhaps, "Artemus" may develope more practical information in future instalments. We add to this extracts from our daily local contemporary giving rules believed to have been framed by the late Mr. Cameron.

THE SAU TREE.—Mr. J. S. Gamble writes to the *Indian Tea Gazette*:—"With reference to your article on the Sau tree as a tea fertilizer, in your issue of January 20th, will you allow me to suggest that perhaps the influence of the tree is after all not due to any chemical action, but merely, as indeed you suggest in your article, to its light, well distributed shade, and to the very small leaflets causing the drip from it in rainy weather to be less harmful than that from broader-leaved trees. I suspect that these are the real reasons for the better yield of the bushes under 'Sau' to those in the open. In regard to the question of its influence on the soil, might I suggest that some of the gentlemen who are interested in the question should get analyses made of the soil taken from under 'Sau' and in the open, in portions of the garden which otherwise appear to have the same soil, and where the difference in the bushes is noticeable. I think the wood would be a very useful one for teaboxes, but it has one drawback common to all the Albizzia woods—that of having a very large proportion of sapwood, which sapwood is utterly worthless, and decays or gets eaten by insects a once."

COCONUT CULTIVATION.—IT will do brothercoffee good, to come down from his high pedestal of high flown theories, and take a few lessons from his brother the coconut. The plantation of coconut requires the every day presence of the planter on the estate. If he be an observant man, and worth his salt, he will, every day, in his rounds, find something to do, something to supply. Besides the ploughing of the land, and the burying of dry leaves, husks and the tying up of cattle to the trunk, he would soon discover why nuts fall before they are mature, and why some trees seem all of a sudden to grow less productive. The careful attention, in preserving and selecting the best nuts for planting, is no small matter; while the curing of copperah with some knowledge of the effect of heat and wind always enhances their price in the European market. A cocount wants, sometimes, its portion of salt and lime, as human beings want medicine. But ignorance leaves all this, to the mercy of the cooly, or the kangany: while the man who has made the cultivation of coconut his study, knows to prescribe the necessary remedy to prevent decay. To many of our readers a detailed account of cocount cultivation would be but carrying coals to New Castle. It is quite enough for us to say, that coconut will ever hold up its head as remunerative and profitable, when other produce will be on the wane.—Jaffna "Patriot."

DAMASCUS is the oldest city in the world. Tyre and Sidon have crumbled; Baalbec is a ruin; Palmyra is burried in a desert; Nineveh and Babylon have disappeared from the Tigris and the Euphrates. Damascus remains what it was before the days of Abraham—a centre of trade and travel, an isle of verdure in the desert, "a presidential capital" with martial and sacred associations extending through thirty centuries. From Damascus came the damson, our blue plum, and the delicious apricot of Portugal, called damasco; damask, our beautiful fabric of cotton and silk, with vines and flowers raised upon a smooth, bright ground; the damask rose introduced into England in the time of Henry VIII.; the Damascus blade, so famous the world over for its keen edge and wonderful elasticity, the secret of whose manufacture was lost when Tamerlane carried the artist into Persia. It is still a city of flowers and bright waters; the streams of Lebanon still murmur and sparkle in the wilderness of the Syrian gardens.—*Ex. Southern Planter.*

GENERALLY ADMITTED FACTS WITH REGARD TO THE MANUFACTURE OF TEA.

[The following paper has been kindly placed at our disposal for publication. It was found amongst the late Mr. Cameron's papers and appears to have been the maxims which he had acquired during his lengthened experience of tea-making in India. They are of peculiar interest to all planters in Ceylon, as the framework on which Mr. Cameron based the teaching that had so powerful an effect for good throughout the island. It will be seen that they refer *only to hand manufacture*].

1. Leaf is best withered when there is free supply of light and cool air.
2. Wet leaf is better withered in the sun or in the wind than by artificial heat.
3. Dried leaf is not necessarily withered leaf.
4. Under-withered leaf breaks in the roll.
5. Over-withered leaf gives most Pekoe tips.
6. Leaf withered in the sun gives red tea.
7. Under-withered leaf gives a green and over-withered leaf a dark outturn.
8. A bright coppery-outturn can only be obtained from well-withered leaf.
9. Under-withered leaf will take longer to fire than well-withered leaf.
10. Low rolling tables cause the leaf to get broken. Anything under 3 feet high is objectionable.
11. If sap comes too quickly in the roll, it shows that the leaf required more withering.
12. Too much sap makes a knobby tea from the leaf getting into lumps.
13. Small leaf cannot be successfully separated from the large before rolling.
14. Heavy rolling destroys the flavor of the small leaf, but improves the strength of the large leaf.
15. Heavy rolling discolors the Pekoe tips.
16. Coarse leaf requires all the rolling it can get.
17. Contact with iron blackens the roll.
18. The roll will color in any temperature, be it higher than, equal to, or lower than, that of the tea house.
19. In a higher temperature than that of the tea house the color comes quickly; in a lower temperature much lower.
20. At some period of so-called "fermentation" the roll gets warm. In the present state of our knowledge there is no certainty whether to check or encourage that warmth.
21. The roll gets blackened by contact with the air and colors more evenly covered up.
22. Coloring in balls is uneven. Roll spread out over three inches to color gets mawkish.
23. The fermentation proper cannot be brought about without heat. Teas coloured in a temperature below that of the tea-house are not "fermented" in the real sense of the word. "Oxidation" or "coloring" expresses the process more correctly.
24. There is no fixed time for coloring; the proper point is determined by the eye.
25. There is no chemical or other test in use to determine the point at which to stop the coloring.
26. The color of the roll immediately before brisk-firing is about the color of the outturn which will be found in the cup.
27. Pungency or rasp and a light liquor accompany a green outturn.
28. Thickness and a dull liquor attend a dark outturn.
29. Over-colouring produces a soft tea.
30. Care given to the withering ensures good color, care given to the roll ensures strength, but care will not ensure flavor.
31. In the present state of our knowledge there is no method by which flavor can be fixed.
32. Leaf opens out during the coloring, and requires re-rolling.
33. Heavy re-rolling before firing softens the tea. A light pressure to excite a little moisture gives the twist and the polish required.
34. Drying in the sun gives a black and tippy tea.
35. Tea dried in the sun, cups out with a metallic taste.
36. Coloring and softening go on rapidly over slow fires, and are checked by all aglow fires.
37. Quick firing gives a brisker tea than slow firing.
38. The roll spread thick on firing trays gets stewed and dull.
39. The roll has been spread too thickly when the fire cannot be seen through the contents of tray.
40. When three-quarter fired, about half an hour, trays can be safely filled up four deep, and the curing finished over slow fires.
41. Choolas can be constructed to consume one maund of charcoal, or less to one maund of tea.
42. Pucka battying developes nose or aroma.
43. Drying in the sun before packing completely desiccates the tea, but gives it a peculiar flavor.
44. Bulking is better before than after pucka battying to ensure the teas being packed hot.
45. Iron-wire, brass-wire, or bamboo trays are all good for firing, but the two former are better conductors of heat than the bamboo ones, and not liable to get out of mesh.—Local "Times."

(*From another planter.*)

I return proof of "Facts *re* manufacture." So far as firing is concerned, the "facts" refer to choola fires, but 36 and 37 are equally true of machine-firing and so far as 38 is concerned you will remember that the roll was after Kinmond's visit spread thinner on the trays with better results. So far as No. 40 is concerned, I think the tendency is now to have final firing done *slowly*, either on choolas, or in self-acting machines. For the first or three-quarter firing the Kindmond dryer suits those who believe in brisk firing and I think most of our tea-makers do; but it can be done too briskly and it probably is when the fan is run at 700 revolutions per minute, apart from the belief that many have in the superiority of Siroceo and coola fired teas. The saving of steam power alone will very likely cause self-acting dryers to be generally used, particularly when the capacity, as in the No. 3 Siroeco, is doubled at such a moderate increase of price.

It has yet to be seen how the new power worked Jackson's dryer is to answer as regards quality. That it will do quantity there is no doubt, but, should it answer well in all respects, it will be more suitable for the larger factories, and the smaller will probably still find their best and most suitable machine in the Sirocco. Of course, there is a strong temptation where a lot of tea is being made to use the machine that does the most work in the shortest time, but, so far as our experience in Ceylon is concerned the teas fired by the latter class have not given the best results. There seems to be a unanimity of opinion among brokers and dealers at home that our teas are too rapidly fired or too hastily finished, and the sooner we acknowledge that the better, so that we may, keep up our good name instead of having to recover from a bad one. It seems to me very likely indeed that the important process of firing will in Ceylon be done generally by self-acting machines and finished off on choolas, as mentioned in No. 40.

So far as the most of the "facts" are concerned there is not much that is new to those who have for years now been manufacturing tea, but the facts are so clearly and concisely put that they may be of service even to the experienced. To the latter the "facts" point out how far we are from more than a superficial knowledge of the art or science of tea-making. No. 20 shews this very clearly as also does No. 25. We know nothing more than what the eye, the touch, and the nose has told and is telling us. It would no doubt be a great step if "fermentation" was scientifically studied and we had an explanation of the change that takes place and its progress up and down the scale; and it would be as great a step if we had the tests to know when the "coloring" should be stopped.—*Ibid.*

FACTS RE TEA MANUFACTURE.—Mr. Scovell of Strathellie, to whom we sent a proof of the late Mr. Cameron's memorandum published yesterday by us, writes:—

I have only noticed two points on which my experience does not tally with the "admitted facts," though, for the most part, you will see that I can speak in support of them.

Mr. Scovell's comments are drawn up as follows:—

1. Leaf is best withered when there is a free supply of light and a circulation of *warm* air.

5. I have not found this. An over-wither results in the breaking of leaf, increasing the Pekoe tips.

14. Heavy rolling destroys the *appearance* of small leaf

but increases the strength without taking from the flavor of the tea.

18. Excessive temperature is against good fermentation.

20. The aim should be to keep the temperature as even as possible during fermentation.

30. Care given to the withering is a step towards good color, but will not ensure it. Great strength cannot be obtained from a poor jât of plant, notwithstanding heavy rolling.

41. Bulking is better carried out after final-firing, as that operation may of itself be uneven. Tea final-fired just before bulking retains sufficient heat for packing purposes. It is not desirable to pack tea with too much heat in it.

Strathellie, 30th March, 1885. ARTHUR E. SCOVELL.

In yesterday's article we find we spoke of Mr. Cameron as having been 30 years in India. In reality he had only been 18, and we ought to have said that the Memorandum left by him was the accumulated and concentrated experience of 30 years' manufacturing on Indian estates by Mr. Cameron and others before him.—*Ibid.*

VEGETARIANISM.

Professor Mayor, of the Cambridge University, the president of the Society, at a recent meeting of the Vegetarian Society, in Exeter Hall, London, said: —The Vegetarian Society, whose history, scope and operations I am told to describe in ten minutes, surveys mankind from China to Peru. It appeals from the barbarisms of civilization to ideal man eating in Eden of the seed-bearing herb, grains, and pulses, and the fruit-bearing tree. It labors for the advent of that reign of peace when none shall hurt or destroy in all the holy mountain The Vegetarian Society draws its witnesses from the sacred books of all nations, from poet and historian and sage. Pythagoras, Zeno, Socrates, Epicurus, Ausonius, Seneca, Plutarch; the men of Plutarch, Curius and Fabricius; the simple races who triumphed over luxurious empires; the Persians of Cyrus, the Greeks of Leonidas, the Roman porridge eaters, *pultiphadi*, the Swedes of Gustavus Vasa; the modern Chinese, Japanese, Turks, Zulus; the miners of Chili, the Hudson's Bay tappers, the Hindu and the Russian, the porters of Smyrna; these are but a sample of the evidence collected by Dr. Lambe, Sir John Sinclair, Sylvester Graham, John Smith, of Malton, Howard Williams and Robert Springer. The baits by which our recruits have been drawn are various. There are Bible vegetarians; the Bible church in Salford and in Pennsylvania makes vegetarianism and teetotalism a part and parcel of its church discipline; there are scientific vegetarians; there are vegetarians from benevolence; there are the æsthetic vegetarians. As a matter of taste they would cleanse our thronghfares from shambles, they would release our women from handling bleeding carcases. There are vegetarians from thrift. Some twenty years ago Dr. Edward Smith and Dr. Guy found the one that our laboring population and the other that our soldiers in hospital throve in inverse proportion to the cost of their diet; surely old Hesiod said truly, "The half is more than the whole." There are experimental vegetarians converted by observation. There are vegetarians from necessity; they have exhausted the specifics of the physicians, and in despair return to nature. Dr. Beketoff, rector of Petersburg University, declares that the future is with vegetarians. And the reason is plain. Ten of us can live where one flesh-eater would starve. Increase the demand for vegetable products and the supply increases and the price falls; increase the demand for animal products and the supply diminishes while the price is enhanced. Carey, the American economist, strongly insist on this law. Take a few examples of animal substances displaced by mineral or vegetable: steel pens have superseded quill, paper has superseded parchment, wood has superseded horn, cotton, linen, paper have displaced wool, silk and feathers, gutta-percha and indiarubber have displaced leather, gas and electric light have displaced wax, tallow, and whale oil. Animal power has been displaced by steam, and electricity and gas, wind and water, tides and solar heat. The saddle horse has been displaced by bicycles and tricycles. Butter has given place to jam and vegetable oils.—*Australasian.*

PLANTING IN NETHERLANDS INDIA.

(*Translated from the "Straits Times".*)

Java Coffee.—Under this heading a communicated article appears in one of our Mid Java contemporaries, pointing out that in no country throughout the world is such good coffee produced as in our colonies. Other countries, such as Brazil, yield it is true heavier crops of coffee but not a better sort. Moreover in Java sufficient labour is available, while Javanese who are born and raised in the coffee districts are better informed as to its cultivation than many Europeans. The main consideration is thorough curing, and this does not depend on good mechanical appliances but on good drying of the coffee. The lowness of the prices now ruling is the result of over production, but when once the coffee leaf disease makes its way into Brazil, Java coffee will once more take up its old standpoint, and those who have sunk their money in coffee estates will, in the writer's opinion, realize enormous profits within a few years.

A correspondent of a Java planting newspaper, in drawing attention to the ravages of leaf disease in Ceylon, lays stress on the circumstances that nothing has been done officially to trace out the so far unknown sources and causes of that disease in Java, where, sometimes, healthy looking estates are suddenly attacked within two days, the disease all at once showing itself on all the coffee trees, there being every likelihood, should matters go on in thway, of enormous losses being incurred by the planting interest.

Gutta.—From Batavia, a correspondent writes to us as follows:—It will doubtless be remembered how the circumstance that the greater demand for gutta percha for industrial purposes in connection with the wasteful way of getting that article in the jungles it is found, has everywhere given rise to serious anxiety lest the stock of it might run out. As the best gutta comes from old trees the cultivation of gutta percha trees is seldom an object of pursuit by means of private enterprize, from its being hard to raise capital for the purpose, owing to returns on it having to be awaited such a long time. Hence it is that the Netherlands India Government has taken the matter in hand, as others had done, and even, not long ago, sent Mr. Burck of the State Botanical Garden here, on a mission to Sumatra to carry on researches regarding this kind of tree, the results being embodied by him in an interesting report. He, however, did not confine himself to purely scientific investigations, but also brought with him seeds from admirably suitable and mature trees, and successfully sowed them in the State Botanical Gardens. The seedlings throve splendidly in the nurseries, and at the setting in of the present West monsoon had to be transplanted into open ground on lands set apart for future Government gutta percha forests. For that purpose, three hundred guilders a month were required for several months. The Governor-General has however declined to sanction the outlay.

Sugar.—The Surabaya Sugar Growers' Association has memorialized the Governor-General of Netherlands India in favor of deferring for two years the levy of excise taxation on Java sugar estates due in 1885 and 1886, on the ground that if their application be granted confidence would return and capital become more readily available; otherwise Chinese capital will take the place of European capital. If State aid be refused them, there is said to be every ground for dreading a commercial crisis this year in Java far worse than that at the end of last year.

A novel source of Government revenue will shortly be turned to account in Java, by farming out the right to collect turtle's eggs on the seashore within

the Preanger Regencies, but only during certain months of the year, the remainder being a close season. The farmer is bound to fence in the abiding places of the turtles, to counteract their destruction by beasts of prey.

Samarang, 28th February.—Now and then slight shocks of earthquake are felt here. There is no longer any doubt of it that increased volcanic activity is disturbing the ground in Java.

Shortly after the Krakatau outburst in 1883, Messrs. Ransomes, Head, and Jeffries of Ipswich, sent out four ploughs to the stricken districts in Java for the benefit of the suffering people. Three of them were sent to the Resident of Bantam, who reported unfavourably on them after trial, on the ground mainly that these appliances were too high priced for the natives, besides being much too heavy, so that a helper is always required to work them and two draught buffaloes are indispensable to draw each plough. When it is borne in mind that the Javanese plough is so light as to be directed by a child it is no wonder that the natives are by no means taken with the English article.

NEW PRODUCTS.

(*From our London Correspondent.*)

As I mentioned in a recent letter, a more favorable report has been received on the prospects in Mauritius, but, so far as I can gather from outsiders, sugar planters generally take a most gloomy view of the situation, and Mr. E. H. Edwards, formally of Rangala and Madulsima, but now of the Seychelles, has been endeavouring to revive their drooping courage and energy by pointing to the example of Ceylon and recommending them to go in for all kinds of new products. There, however, as elsewhere the practical question at once arises where is the necessary capital to come from for substituting these untried industries for the old one which now proves unremunerative except on unencumbered estates possessing the most efficient crushing machinery and appliances.

I have had a talk this week with an enthusiast in the matter of COCA cultivation, who contends that it would well repay Ceylon planters to put down a few acres in suitable localities since the European demand for the leaves is now considerable and rapidly increasing whilst the supply from South America is wholly inadequate. At the moment there are none obtainable here, and fancy prices from 6s to 12s per lb. would readily be paid by manufacturers of cocaine who are unable to complete orders for the anæsthetic except for the most delicate operations on the eye or throat. The price of the drug is practically prohibitory, whereas if it were cheaper, there would probably be a large consumption for the use of neuralgia where it is said to be very effective. Moreover a tonic said to possess wonderful restorative properties is prepared from the leaves, and Adelina Patti has declared that she attributes the retention of her marvellous local powers to the fact that she has for a long time past taken a dose of this coca tonic every morning. It is true that there are not many who would hope to rival the prima donna even with the help of coca, but such a testimonial is sure to create extensive enquiry amongst the very numerous class of persons of both sexes who do or imagine that they suffer from nervous affections. My informant was of opinion that 2s 6d per lb. might be regarded as the normal price of good leaves in this market for a considerable time to come, and, as the cultivation is easy and the plant bears a crop in eighteen months, it might really be worth while for some Ceylon proprietors to add this to the several products now receiving attention. I learn that a planter in the Madura district of South India is buying up all the plants and seed he can lay hands upon with a view of establishing a coca garden there. By the way, either a copious natural rainfall or artifical irrigation appears essential to the plant. Great care must be taken in the selection of locality.

Comparatively little attention seems to be paid in Ceylon to RHEA culture, but elsewhere in the East this is not the case, and amongst Manchester spinners there is now a firm conviction of the value of the fibre and feasibility of growing it to advantage. Sir Joseph Lee and other practical men engaged in the textile industries have recently visited the establishment at Soubiers near Rouen owned by the Lini-soir Syndicate, and they report most favorably upon the results achieved by the Faviers-Fremy processes in operation there. Certain changes have been made in these which obviate the difficulty previously found, and they are now declared to have solved the problem of utilizing Rhea fibre. As a consequence the Johore Rhea Company will shortly be brought out under influential auspices and a large tract of the land sold to it by Mr. Edwin Watson will be planted up, the experimental trials under his superintendence having proved a signal success. A license to use the Faviers patent has also been taken for China by a gentleman formerly connected with Ceylon, and his agent starts by the next French mail to complete arrangements for encouraging the cultivation of China grass in the neighbourhood of Hankow to be treated by this process.

A NEW FOOD.—There can be no discovery of greater importance than that of a new article of human food. Such a discovery is announced from Cochabamba, in South America, by M. Sace, who is exploring there. There are, it seems, some of the varieties of the cotton tree peculiar to Bolivia, the seeds of which are the richest of all known grains in nitrogenous substances. The flour, it is said, is likely to take an important place in human alimentation, as it is suitable for the preparation of all kinds of pastes, and may even be available as a substitute for milk. Nothing is said of its smell, savor, or general palatableness, but a good cook should be able to make it presentable whatever these may be. The presence of the nutriment is the main question, and it should, to render it of economical value, give a good yield per acre.—Melbourne *Leader*.

THE INDIAN TEA TRADE.—The Calcutta *Englishman* has the following on the China tea trade:—"The results of last year's tea operations tend rather to confirm the gloomy prophecies of the merchants. All have lost on the whole. Not only have they earned no commission or profits, but there has been a decided shrinkage in the capital embarked. One veryprominent merchant here, who handled nearly £240,000 worth of tea during the past season, only made two paying shipments. The remainder lost very heavily, and the whole season shows a loss of fifteen per cent on the money engaged. The Australian market is no better, but several Foochow tea men have gone there to try and beat up a market by "drumming" for small orders at a low commission. The tea merchants have come to the conclusion that the firm in whose hands the cargo boats chiefly are, make too much, considering their own inability to make both ends meet, and proposals are in circulation for the formation of a co-operative cargo boat association, but the want of cohesion and spirit will probably secure the continuance of the present monopoly."

THE SARDINE:—The fish referred to by the Calcutta *Englishman* in the following paragraph abound round our own shores. Is there not the possibility of a similar industry being established in Ceylon?—"The sardine, like champagne and port wine, constitutes one of that large class of articles as to the authenticity of which it becomes the prudent man, in these progressive times, not to inquire too closely. This caution may be the more confidently recommended for acceptance owing to an announcement which comes from Madras that a Frenchman has discovered a method of preserving a fish found in great abundance on the Malabar Coast, which is described as being "either the real sardine, or very much like it." This fish frequents the coast in question in such large numbers that it is said an entire boat load may sometimes be purchased for four annas. In such circumstances it is not surprizing to further learn that it is used as manure. It is now, it seems, destined for a higher end. Preserved in neat tins it will appear in a more becoming guise, and innocently figure on our breakfast table as the genuine product of the waters of the Mediterranean. It is some consolation that with the opening out of so rich a source of supply the price of sardines should go down."

THE BONUS SYSTEM ON TEA GARDENS.

At a meeting of the Indian Tea Districts Association, held on the 25th Feburary, the above question referred to in the following circular was discussed:—"Coolie Bonus, Calcutta. Jan. 26, 1885. Dear Sirs,—With reference to the General Committee's circular, dated 15th inst., on the subject of Coolie Bonus, I am directed to hand you the following resolutions, which it is proposed to submit to the general meeting of the Association to be held on Feb. 26, 1885. Agents in Calcutta are invited to obtain the sanction of the proprietors whom they represent both in India and England, to enable them to support the resolutions in question. 1st. That the payment of a Bonus to time-expired coolies on re-engaging, or to coolies engaged from other Gardens under the Rules of the Association, be entirely done away with from Oct. 1, 1885. 2nd. —That no Garden shall employ time-expired or "falto" coolies from Gardens belonging to the Association until a period of one year shall have elapsed from the time of their leaving the Garden on which they were last employed.—Yours faithfully, G. M. BARTON, Secretary.

It was proposed by Mr. A. B. Inglis, seconded by Mr. J. Berry White, and carried unanimously, "That this Association, while approving of an effort being made to do away with the Bonus System, hesitates at present to agree to its total abolition. It recommends that, in the first instance, the bonus should be reduced, leaving the amount of such reduction to be fixed by the several district committees, care being taken to get districts adjoining each other to act together in the matter, and to give effect to any change agreed upon simultaneously.

With regard to the second proposition referred to in the circular, it was porposed by Mr. W. Roberts, seconded by Mr. R. Lyell, and carried unanimously:—"That this Association desires to express its dissent from the second proposed resolution forwarded from Calcutta."—*Home and Colonial Mail.*

FORESTS AND CLIMATE.

At a meeting of the Meteorlogical Society of Berlin, held on January 6, and reported in *Nature*, Professor Müttrich gave a short historical review of the arrangements in connection with forest meteorological stations in Prussia, seventeen of which were in operation. They were established on as uniform a system as possible over regions of very wide varieties of climate, on plains and at different levels above the sea, in districts having a more continental, and in districts having a more oceanic climate, and in leaf and Pine forests. In all these places, moreover, observations were made according to precisely the same regulations. Each station was twofold, having one equipment in the wood, another in the open field, both as a rule at the distance of 200 metres from the edge of the wood. The observations comprised the atmospheric pressure, the temperature of the air and of the ground, the wind, moisture, cloudiness, atmospheric precipitation, and the evaporation of an open mass of water. These observations were made twice a day—at 8 A.M. and 2 P.M. The observations thus obtained were collected at the station of Eberswalde, and published regluarly in monthly and yearly reports.

As a result of his investigation, Professor Müttrich had arrived at certain definite conclusions respecting the influence of the forest on temperature, which may be stated as follows:—(1), The forest exercised a positive influence on the temperature of the air; (2), the daily variations of temperature were lessened by the forest, and in summer more than in winter; (3), the influence of the leafy forest was in summer greater than that of the Pine forest, while in winter the tempering influence of the Pine forest preponderated over that of the disfoliaged forest. An attempt to determine the influence of the forest on the mean annual temperature led to no sure results.—*Gardeners' Chronicle.*

NOTES ON PRODUCE THE TEA TRADE.

A reform in the customs of the tea trade are being advocated in some quarters. The present system of deposits and payment for tea is thus condemned by the *Grocer*:—The terms now recognised in the tea trade for buying and selling are the same as have been in force for the last 50 years or more, and the merest tyro in the wholesale line knows very well that in other respects immense changes in the mode of conducting business have taken place during that period. The value of tea in, say, 1830, when the Customs duty alone was 2s. per lb., was much greater than it is now, and a deposit of £1 per chest was of less significance than at present, when it is almost enough by itself to pay for the article bought. As, therefore, the deposits on a parcel of tea of different sized packages represent a larger proportion of cash payments than they did in former years, the risks attending a tampering of warrants are multiplied fourfold, and in case of a dispute as to who is the rightful owner of the tea when the buyer has paid the required deposit, and the warrants are in the custody of a second or third party, it would be a very nice point for the lawyers to settle among themselves, if not to the entire satisfaction of the unfortunate disputants. These would be the importers and their selling brokers, the bankers who find the requisite financial accommodation pending the final disposal of the teas, the wholesale dealers, and their friends the retailers. All would claim some ownership, and if the goods had partly passed into the hands of buying brokers as well, the question would be still more intricate and complicated. Anyone who is the least conversant with the trade can, from his own experience, easily picture to himself the consequences which must inevitably arise from tea warrants getting into the wrong hands when immediate delivery of the goods is demanded for the consumer. The delay and inconvenience to the retailer would also be a very serious matter, and anything that can be done to obviate one or the other ought to receive the approval of the whole trade. For instance, deposits might to abolished altogether, the same as they are practically on sugar and coffee, and instead of the prompt on tea being three months, as now, it might advantageously be shortened to one or two months, with the allowance of a discount when payment is made punctually on the prompt day. The import merchant not having to wait so long for his money, would not, as he often does now, have to seek the assistance of his broker, and what he pays him would, we should imagine, more than suffice to allow the dealers a fair discount on all payments made prior to the day of prompt. If an honest and timely effort is made to work out some reform in the system of dealing in tea, more security in their position as holders will be felt by both buyers and sellers, and future disputes and entanglements may be happily avoided.—*Home and Colonial Mail.*

PLASTER.

BY SIR J. B. LAWES, F. R. S.

The influence of plaster upon clover and other leguminous crops has been explained in a variety of ways, none of which are quite satisfactory. Quite a new explanation has been brought forward by a French chemist. M. Pichard has been investigating the action of various compounds upon the nitrification of the organic matters in the soil. He tried the sulphates of potash, soda, magnesia, also chalk and gypsum, and found that gypsum nitrified the organic matter to a far greater extent than any of the other substances; gypsum being 100, the other substances would range from 45 to 12½. Another French chemist, M. Joullie, has been investigatiog the loss of ammonia which takes place during the fermentation of barn-yard manure. He says there may be a loss of 20 per cent of the ammonia. this loss being due to the decomposition of the ammonia contained in the drainage water, and this loss is largely increased by the addition of plaster. If this be true, the beneficial effect of plaster, when used in stables, must be due to the destsuction, and not the fixation, of ammonia. M. Pichard considers that the beneficial influence of gypsum upon Lucerne is

due to the nitrification of the soil; but there is a difficulty attending this explanation which is not easily got over. The cereal grain crops are especially benefited by the application of nitrates, but plaster is rarely found to be a good manure for these crops. M. Pichard's experiments were carried on upon a very poor soil, the organic matter of which would not nitrify without the addition of some ferment. We have found it very difficult to nitrify the organic matter in our subsoils at Rothamsted; if, however, the gypsum, when carried down by rain-water, would set up a nitrifying action in the subsoil, such a fact would be of considerable value in accounting for the source of the nitrogen in these plants. In the papers which we read at Montreal, both last year and this year, we have brought forward a good deal of evidence which bears upon this very complicated subject. With plants which take their food not very far from the surface of the soil, we can, with great care and attention, determine by analysis of the soil the losses which have taken place by the removal of crops. When, however, the roots of plants extend several feet below the surface, as is the case with some of the leguminous plants, and the influence of these roots extends some considerable distance below their extremeties, all our efforts to measure the loss which takes place in a soil has hitherto proved ineffectual. Greater exhaustion of the soil by the continual removal of these crops, and more accurate processes for the analysis of soils, may in the course of time find a solution; in the meantime it is satisfactory to know that upon all soils upon which plaster was applied increased the growth, and the cultivator provided for his cereal crop a supply of nitrogen much more cheaply than by any other means, and even when plaster fails he may have recourse to kanit salt with some considerable prospect of success.—*Southern Planter.*

CURING TOBACCO BY OPEN FIRES AND SMOKE.

The log barns for curing dark and strong tobacco with fire and smoke, as they were constructed in colonial times, are still common. These barns are built of straight logs about eight or ten inches in diameter, and usually about twenty feet long. They are put up in the form of a square pen, and notched down at the corners so as to touch each other. About seven feet from the ground the first corner of tier-poles are put, resting on the logs on opposite sides, and four feet apart. As the body of the house is built up, at each three feet another course of tier-poles are placed vertically over those below, and so on until the body of the house reaches the desired height—generally about twenty feet. Hewn plates are then put on, and upon these the feet of the rafters rest. The rafters are so framed as to have an elevation of forty-five or fifty degrees, and they are placed over the line of the tier-poles, and are strengthened by cross-ties nailed strongly on opposite sides. These ties are also placed the same distance apart as the tier-poles of the body, and ranging vertically above them afford the means of hanging nearly as much tobacco in the roofs as in the body.

The covering of the roof is now usually of shingles, or with planks placed vertically, with the joints covered by other and narrower planks.

After the house is completed, a door is cut on the south side, and a proper shutter made and hung by wooden or metallic hinges. The space between the logs should be *daubed* with clay to the height of the first line of tier-poles, and if the logs are properly notched, no daubing will be needed above. The openings between the logs will afford ventilation for *drying* out the tobacco when necessary, and bringing *in order* in damp weather when it is desirable to *strike* and place it in bulk. The tobacco, when it is cut from the field, is hung on sticks riven from straight-grained timber, four and a half feet long and about an inch square. These sticks, when filled from six to twelve plants each, according to size, are lifted into the barn and hung on the tier-poles, commencing in the roof and working downwards; and when the house is filled, the firing may commence at once, or be postponed a day or two, according to weather and other circumstances. The fires are always made of *green* or half-seasoned logs, cut about six or eight feet long, and of a size that man can lift and carry into the house. These logs are laid end to end in *three* parallel rows, and three or four together, the rows being about six feet apart. Small fires are kindled under and between the logs at short distances with some dry material, and when the logs commence burning the fires are kept up by adding other logs. Care is taken that the fires are kept slow at first, generating more *smoke* than *heat*; but as the tobacco begins to dry, more heat is given until the leaf and the lower part of the main stem is well cured. This process requires great care to prevent a conflagration. In its last stages the leaf becomes almost as dry as tinder, and a few strong sparks generated by careless handling of the fires will in many cases cause the destruction of the barn and contents.—*Southern Planter.*

AN INVITATION TO JAVA.

The study of vegetable anatomy and of the physiology of tropical plants cannot be carried out on an extensive or satisfactory scale at home, where the specimens are few, and grown under glass. In order to thoroughly investigate the growth and progress of these plants, it is necessary to have abundance of material at hand in all stages of growth. This want is to be supplied by the spirited enterprise of Dr. Treub, the Director of the famous Botanic Garden of Buitenzorg, Java. Dr. Treub, invites European botanists to spend a few months in Buitenzorg, where literary and every other facility is afforded for their investigations. Dr. Treub has, with the consent of the Dutch Government, established a physiological laboratory. The usual reagents, small bottles necessaries for work, are placed at the disposal of the botanists. Alcohol, bottles, and herbarium-paper, which the visitor may wish to use for his collections, will be furnished at the expense of the visitor. Dr. Treub will assist the investigations by procuring materials for investigation, and by furnishing any information desired. The botanic garden proper, founded in 1817 by Professor Reinwardt, consists of 91½ acres, and contains more than 9,000 species; each species is represented by two plants. The directorate consists of a director and a sub-director; the garden work is carried on by a head gardener and an assistant gardener and by several native workmen. The agricultural garden is 6 miles from Buitenzorg. This garden contains 172 acres, and was founded in 1876. Another botanic garden is situated on the slopes of the volcano of Gedeh, at an elevation of about 4,500 feet. The botanical museum, in the centre of Buitenzorg, near the garden, contains the herbarium and a collection of vegetable productions preserved dry and in alcohol. The same building contains the library and the garden offices. A small place in the museum ground is reserved for drawing and photography.

Buitenzorg is situated in one of the most beautiful part of Western Java, and about 36 miles from Batavia, at the base of a great mountain, Salak.

There is an idea that people visiting the tropics are necessarily subject to serious maladies, but this is erroneous, especially with regard to Java. The chances of illness are less than those entailed during a winter in Europe. Dr. Treub does not pretend that a stranger going to dwell there for four or five months cannot fall ill, but he asserts that the chances of taking a serious illness are not greater than if he stayed at home or travelled in Europe during the winter.

The best time for a botanist to visit Buitenzorg is from October to April. It is the wet season, and the heavy and frequent rains are sometimes troublesome, but it is the coolest and the healthiest season, and the one in which vegetation is most luxuriant. Moreover, even in the rainy season, it seldom rains before midday, and as for the so-called dry season rain is very frequent, for a continual drought, as in the east of Java, is unknown in Buitenzorg. The temperature is not so high as represented; the maximum at midday is between 28° and 29° Cent. (83° to 85° Fahr.) in the shade. In the dry season the thermometer reaches 31° Cent. (88° Fahr.) The evenings, nights, and mornings are fresh,

temperature varying between 22° and 25° Cent. (72° to 77° Fahr.) The cost of living in Buitenzorg would not exceed 450 francs per month (£18). This includes hotel and excursion expenses, but if it is intended to travel in the interior of Java the expenses will be increased considerably. But there is no need to go far from Buitenzorg to get a good idea of tropical vegetation. Six months would be long enough to spend in the Garden of Buitenzorg, and it should not cost more than 5,000 francs (£200). Dr. Treub suggests that scientific societies and like associations should assist the botanists of their countries to pass a few months in Buitenzorg.—*Gardeners' Chronicle.*

SULPHIDE OF POTASSIUM AS A REMEDY FOR PLANT DISEASE.

Various applications of sulphur have been used from time immemorial for the destruction of mildew and red-spider, generally in the form of flowers of sulphur—an imperfect remedy, the application of which is both inconvenient and unsightly. Some old gardeners recommend quicklime and sulphur to be boiled together, in water; this makes a solution of bisulphide of calcium, which is probably a very efficient form of applying sulphur to plants, but as yet I have not tried it.

The mixture of sulphur and carbon, or bisulphide of carbon, is known to be the best remedy against Phylloxera, but unfortunately it is very sparingly soluble in water (some treatises on chemistry describe it as insoluble); moreover, its odour is most offensive. The odour of the compound of sulphur and potassium (bisulphide, or sulphuret of potassium, the "liver of sulphur" of the old books), which is here recommended, is not agreeable being that of Harrogate water, but it is sweet compared with the carbon compound; however, I gratefully tolerate the smell, in recognition of the multifarious cures it effects in man, beast, and plant. A strong solution (half an ounce to a pint of water) applied to the surface affected, by means of lint or rag wetted in it, is a perfect remedy for many kinds of poisoned wounds, skin diseases caused by vegetable and animal parasites, withlows, and many forms of inflammation involving the formation of pus. I have had thirty years' experience of its valuable qualities in such cases, and I never found it do any mischief in the few where no benefit could be traced to its use. On two occasions gardeners in my employ came to me with poisoned wounds, each with his hand and fingers swollen, and both perfectly stiff, with a red line up the arm, showing extension of the inflammation to the axilla; in each case I applied to the hand a bandage wet with a strong solution, and in each case on the next day the inflammation had disappeared, and the hand and fingers could be moved freely. I make no excuse for referring to this medical phase of the subject, for independently of the liability of gardeners to the accident referred to, the action of the potassium compound of sulphur on animals is of the same character as its action on plants, and what is very important, to neither, even when no direct benefit can be traced to its application, it does any harm, even to the most delicate plant, when plunged overhead. Plunge soil and pot in a solution of a quarter of an ounce to the gallon (I have frequently used half an ounce to the gallon without mischief, but a quarter of an ounce is sufficient); I have saturated every Orchid, filling two houses, without a trace of injury to foliage, pseudobulb, or root; in fact, the growing points of the roots appear more active after the dose. As to the benefit to plants to be derived from its use, it arrests at once all forms of fungoid growth—even the hard fungus which grows on dead wood; it is a perfect remedy for mildew on Roses, &c. I have found it efficient against red-spider; it is probably equally so against microbes, various forms of which are doubtless as injurious to plants as other forms are supposed to be to animals. It will probably relieve us from those diseases which are so destructive to the bulbs of Lilies, Eucharis, &c. My limited experience has already proved that it has arrested disease in many varieties of plants. I was driven to the necessity of taking some active steps to counteract a form of disease, which had become endemic with me, the marked symptom of which is rotten roots. As this has increased so much of late, and had begun to attack every plant in my houses (a great variety), I began experimenting at the beginning of this winter very carefully with the sulphuret of potassium, and growing bolder as I traced no injury to its use, I ultimately applied it to nearly all my plants. I should have postponed writing until after an extended experience during the growing period of the year; but I thought that some benefit might arise from others joining in the experiment, even if they limited themselves to testing its effect upon that very troublesome disease, mildew on Roses, which so frequently puts in its appearance at this season of the year. The compound is cheap—I pay 8*d.* per pound for it; it is very soluble in water, and is easy of application.—Edmund Tonks, Warwickshire.—*Gardeners' Chronicle.*

THE MANUFACTURE OF INDIAN TEA.

"Spectator" writing to the *Statist, apropos* of an extract from Messrs. Gow and Wilson's annual review of the tea trade, which has appeared in our columns, relative to tea manufacture and deterioration in quality of Indian tea says, "There is doubtless a measure of truth as regards the deterioration in quality of Indian teas, resulting from a lack of scientific knowledge of the requisite conditions of manufacture. It must not be lost sight of, however, that although this applies to many of the older and possibly best-known tea concerns, it certainly is not the case on a large number of the more modern and better administered estates—just those where machinery is most largely used. On many of these estates, all the processes of manufacture have now for several years been the subject of most careful study by a large and intelligent body of planters, many of them men of high social standing and good education. While, then, it is undoubtedly the case that there is produced much tea, on the manufacture of which a minimum of intelligence and skill is bestowed, on the other hand a very considerable minority at least of the estates produce teas of high-class merit, such merit mainly attributable to the care and skill bestowed on its preparation. Owing to the large quantities of leaf which at the height of the season have now to be dealt with, when weather is unpropitious, quality is often unavoidably inferior. In factories, however, where a good system prevails—where there is an intelligent manager, a sufficient staff of well-trained sirdars and coolies, and where adequate machinery and sufficient withering accommodation exists—the evil effect, even of unfavourable weather conditions, is reduced to a minimum. As proof of this, it is only necessary to point to certain well-known factories which continue from year's end to year's end to produce uniform high-class quality, and obtain regular "long" prices for their teas.

"As regards your allusions to points of detail:—Withering Leaf.—The application of artificial heat to raise the temperature of the "leaf-houses" has often been tried, and in many quarters this is now done at the height of the rainy season. Almost all planters, however, are agreed that this is not conducive to high-class quality, and is only resorted to as a last resource. Several machines and processes have been invented and tried for the artificial withering of the leaf, and although it is possible that some suitable system for drying the air, without absolutely heating it, may yet be found, yet so far no satisfactory method has been discovered. It is, however, of course, fully recognised that the withering process is the most crucial one in manufacture.

"Firing—Your able correspondent's assertion—that the whole secret is, 'the tea must not be calcined'—is, I venture to say, scarcely the whole truth. The secrets of high-class manufacture are multifarious; they consist in a most careful attention to every component part of the process, from the moment it commences till the time the tea is finally 'fired off.' As regards, however, the duration of the process and the temperature at which it should be done your correspondent raises a point which at this juncture deserves the attention of all planters, and is well worthy of full discussion. Since the introduction of machinery, there has undoubtedly been a tendency to too rapid firing at an extreme temperature. More recently,

however, the more intelligent planters are reverting to slower firing at a lower temperature. The question, however, as between the two methods is a matter which, I venture to say, is still *sub judice*.

"With the large quantites of tea which have now to be dealt with—large factories and large outturns—machinery is absolutely indispensible, and must needs, ere long, be much more largely utilised. You are accordingly, I feel sure, doing a benefit to the industry in directing attention to the important question of quality; and the suggestion that a better knowledge of chemistry would be advantageous to those engaged in the practical operations of tea-making is a good one. Never, perhaps, more than at the present moment was 'market' more critical of the quality of the teas which are offered them."—*Home and Colonial Mail.*

BLACK PEPPER.

Some of our readers wish to know more about the pepper, that is always on every American table that supports a castor, than the mere fact that it is a tropical product, and is grown chiefly on the spice islands south of the Asiatic peninsula Well, we wish to please, as well as to instruct our readers.

Black pepper was for ages considered a very choice article. Like gold, silver and precious stones, it was for many generations found only on royal tables, and those of the rich and noble who aspired to rank with the rulers of the realm. Choice spices and rare gums were among the precious treasures of the kings of Eygpt more than two thousand years before the Christian era. The trading Midianitic caravan that purchased Joseph from his brothers and sold him into Egypt were bearers of "spicery and balm" for the Egyptian market. And when the sons of Jacob were making preparations to visit that land the second time, to propitiate the "Lord of the realm," their father said to them: "Take of the best fruits of the land, and carry down a little balm and a little honey, spices and myrrh, nuts and almonds." Indeed, during the palmy days of Egypt, when they embalmed all their distinguished dead, precious gums and fragrant, pungent spices were largely called into requisition. Even the Israelites, in their ritualistic worship, held in such high esteem many of these rare gums and oils that their law forbade their use for any other purpose.

It is not, therefore, surprising that during the first centuries of the Christian era even the common spice, which is known as black pepper, was prized as highly in the city of Rome as its weight in gold.

When this pepper was first discovered it was growing spontaneously as a kind of wild vine. It was found in narrow, well-wooded valleys, where the soil was rich and moist, the air hot and humid. Such conditions are found in Southern India, Java, Sumatra, Sierra Leone and Isle of France. It grows on vines—not unlike grapes, but much smaller, which creep along the ground, and frequently throw out new roots. It is most successfuly cultivated under tall trees, which secure for the vine, shade and support. The vine may be cultivated and trained to ascend large trees, into whose rough bark it fastens its roots or tendrils. Where the soil is deep, rich and moist, these vines will often reach a height of 20 to 30 feet. Though for convenience of gathering, they are seldom permitted to grow much higher than a man's head. The leaves are oval and the blossoms white. When these fall the berries grow on the stem that is left, and this spike of a vigorous vine will bear from twenty to fifty berries. From green they turn to red, and when they attain a dark chocolate shade, they are deemed mature, and the spike is pinched off and placed on mats, or on hard, dry, smooth ground in the sun or in open baskets before a gentle fire a few days. They are then cleaned and ready to be placed in mats or sacks which are called piculs. Each of these, when well filled, is supposed to weigh 133⅓ pounds.

Spices of all kinds, like teas, coffee and fruits of every variety, are greatly improved by cultivation and wise, skillful attention. The migration of Chinese and Europeans to Southern Asia, Malacca and the Spice Islands, who have given special attention to the growth and cultivation of pepper have greatly increased its production and intrinsic value. Yet, at the same time, they have learned that it is possible to mix up with the pure berry the pepper stems, pieces of the vine and other material, which, when pulverized, taste and smell so much like pepper, that none but an expert can intelligently affirm that the product is either impure or adulterated.

But conscientious and honorable men, who own and run mills for grinding pepper, as carefully screen the pure, round pepper berry from stems, vines, dirt and rubbish of all kinds, as a good miller does wheat and corn from smut, cobs and all foreign material, before they pour these grains into the hopper.—*Independent Journal.*

SPIDER-SILK.

There are many more things in heaven and earth than are dreamt of in our philosophy, although a hackneyed truism, is of special application in the domains of science. Natural history supplies instances where the wildest dream of the visionary has found a resting-place in the ordinary occurrences of life. From the period of the legendary introduction of the silk-worm into Europe by a pious fraud of the Jesuit Fathers down to a comparatively recent date, the spirit of enquiry has never slept in regard to the progressive display of silk-producing insects. It was, however, reserved for the Society of Arts to lend encouragement to investigations in this direction, by awarding a medal to one Mr. Rolt for his success in obtaining an appreciable quantity of silk from the garden spider, and thus inaugurating a new and important era in the annals of commerce. That gentleman accomplished his purpose by connecting reel with a steam engine, setting it revolving at the rate of 150 feet per minute; when, after two hours' patience, he wound off 18,000 feet of beautiful white line of a metallic lustre from twenty-four spiders. Subsequent examination proved this thread to be only the 30,000th part of an inch in diameter, so that a single pound weight was estimated to be sufficient to encircle the globe. This was about fifty years ago, and Mr. Rolt's experiments were not pushed further. It was reserved for a Frenchman to manufacture gloves and stockings of spider-silk. But owing to the extreme difficulty of bringing together a numerous family of spinners within a reasonable space, on account of their pugnacity, led to the abandonment of the industry. Certain species of foreign spiders, however, when examined with a view to their silk, offer a field for very considerable encouragement. In the island of Ceylon there is one, two inches long, with a large yellow spot upon its back, which spins a beautiful yellow web 2½ feet in diameter, so strong that an ordinary walking stick thrown in, is entangled and retained among the meshes. As might be expected the filament, which is said to exhibit a more silky appearance than common spiders' web, is easily wound by hand on a card without any care being exercised in the operation. There is another spider of more formidable dimensions. It is a large black, yellow-spotted creature, measuring more than six inches across its extended legs, and it spins a web strained on lines as stout as fine sewing cotton. It is to be found in moderately warm southerly latitudes like New Zealand, Queensland, and the Cape of Good Hope. In habits it is exactly the reverse of its European brother, for, instead of devouring each other, it exists in little harmonious communities of upwards of a hundred, of different ages and sizes occupying a common web. It spins a beautiful yellow net-work about 12 feet in diameter, quite as strong as the silk of commerce. A traveller who had an adventure with it says:—"In passing through an opening between some trees, I felt my head entangled in the meshes of an immense cob-web, which was drawn like a veil of thick gauze across the opening, and was expanded from branch to branch of the opposite trees as large as a sheet, 10 or 12 feet in diameter." Another account says that it sometimes covers an entire lemon tree, and its diameter was estimated at ten yards. But the latest addition to our knowledge of spider-silk comes from the Paris "Ecole Pratique d'Acclimatiou," a member of which has discovered an African species which spins a strong yellow web, so very like the product of the silk-worms as to be scarcely distinguishable from it. This promises to be a fibre of commeece of the future, as after a close

investigation, a syndicate of Lyons silk-merchants has reported in its favour, and the great difficulty of procuring it in sufficiently large quantities for the loam has been overcome by the fact that there is no difficulty in acclimatising the spider in France.—*Indian Agriculturist.* [We should like to see this statement confirmed. Spiders generally are so pugnacious and cannibalistic, that of 60 enclosed for spinning purposes, only half-a-dozen bloated individuals are said to have been found living after the lapse of a night.—ED.]

IMPROVEMENTS IN THE "SIROCCO" TEA DRIER.

Mr. Davidson having set up three of his new "Sirocco" Driers on view at 60, Gracechurch Street, E. C., we willingly availed ourselves of his invitation to inspect them, as we had learnt from him that he had introduced several quite new features in the method of construction which doubled their capacity for work. We found that whilst the old "Sirocco" Driers of the No. 1 and No. 2 B type are easily convertible by the veriest pretence of a coolie *lohar mistrie*, the conversion totally altered the conditions both as to area of trays exposed to the heated air, the application of the heated air, the shape of the drier, and the possibilities in the outturn of dried tea. There was a converted "Sirocco" on view, and two of the latest "Siroccos" constructed on the new system. Dealing firstly with the former, and so many of these being already in use, they merit the first mention. It is surprising to find with what a little trouble the conversion is effected, although the result is so important, and effects a thorough change in the whole principle and shape of the drier. An idea will be gained of the ease with which the change can be effected (on receipt of the new parts which are supplied at the almost nominal cost of £23, the trays being 22s. each extra) by stating that all that has to be done, is to take off the hood and chimney, then place upon the top, so exposed, the end of the long chamber, now supplied. Then the old tray-chamber front is removed by cutting off the rivet heads, and a piece of sheet-iron is fixed in its place by means of screw-rivets, to completely *close* this portion. This is done to allow the heated air to pass up into the new drying-chamber. The holes for the screw-rivets in the new sheet are so placed as to correspond with the old rivet-holes, thus saving all boring. The feeder's-table is then attached to what used to be the right-hand side of the machine, and this is done by removing two of the old rivets at the top to take the table-brackets, or supporters, by means of two screw-rivets. Two little notches have to be cut in the corner irons to take the edge of the table, similar to the old notches, but higher up, of course, as the feeder has now to work with the trays at about 3 feet above the present level of the top of the old "Siroccos." After this there remains but to place the chimney in a new position, at the side of the "Sirocco" by means of new bends, which are supplied for the purpose, and the alterations are completed. The result, for the nominal cost mentioned, is an increase of two-thirds in the outturn. The New Driers, constructed throughout to reap the full advantages of the new principle, will show a still more marked improvement. The new drying chamber takes eight trays, four being on an upper row, and four beneath these. Thus the area is doubled. The heat is so evenly dispersed, that great equality in drying is the result. The waste heat, which formerly was lost up the chimney, is now dispersed from the top of the whole length of the long, new drying-chamber, and thus may be utilised for withering leaf in *machans* overhead. We can only mention a few of the advantages of the new principle, as space does not allow of a thorough description of the totally new departure that has been effected; and the vast improvement, that is at once apparent on an inspection, would take too long to do even partial justice to here. Fermentation is instantly arrested, and the rapid drying which commences at the start, continues to the finish. No motive power whatever is required. The trays require less handling, being only twice lifted from start to finish and hence they wear longer. No trays are required to catch the fine *goorie*. Besides these and the very greatly increased outturn, there have been many practical improvements made in the construction of the stove of the new driers, which have been suggested by past weaknesses, and have been applied after long experience has indicated the direction of perfect success. After this it needs only to be added that the new "Siroccos" not only show an immense increase in working power, but are made of the best materials, under the personal supervision of the inventor at his own works, and they certainly are marvellously cheap, both in regard to the work they can do, and the excellence of their material and construction. Thus the new No. 5, which is in every respect similar in principle to the new No. 4, but double the size being—in fact, two No. 4 driers side by side, but worked by a larger stove than a No. 4—should turn out two maunds of perfectly-dried tea per hour, and its price, complete with trays, thermometer, fire-irons, &c., packed and delivered f.o.b., Liverpool or Glasgow, is only £95. With the Nos. 4 and 5 the drying is effected by fumes from the coke with a mixture of air, though Mr. Davidson, we notice, states in favour of his No. 3 (price £90, outturn 8¾ to 10 maunds dried tea per ten hours) that "It is now a generally accepted opinion that pure air produces a finer flavour in tea than air impregnated with fumes from coke or charcoal, and in this respect only is the No. 4 'Sirocco' in any way inferior to No. 3," in which latter the drying is effected by pure heated air, the furnace being on the same principle as in the old "Siroccos," with certain important improvements. We were informed that no less than fifty of these Driers have been sold within the past fortnight, which speaks volumes for the estimation in which they are held by those who have had an opportunity of inspecting them. No less than 700 of the old "Siroccos" have been sold, so the prospects of being able to improve them at so cheap a rate must be welcome news to many.—*Home and Colonial Mail.*

THE BURLIAR EXPERIMENTAL GARDEN, MADRAS PRESIDENCY.

This experimental Garden is situated on the Coonoor Ghaut, at an elevation of about 2,500 feet above the sea, in a deep and wooded ravine through which flows a powerful perennial stream, diffusing moisture and coolness around a most charming and romantic spot, but unfortunately somewhat marred by a congeries of dirty huts abutting on the road above the Garden, otherwise the situation would be almost perfect, faced as it is, by that most splendidly wooded mountain Hoolicul towering above it in its southern front to the height of some seven thousand feet, and backed to the North by that wonderful rock called the "Lamb;" why, we never could make out, for in its frowning majesty, it far more reminds one of the Lion than of the Lamb. We cannot help paying a tribute to the gorgeous scenery around, though, alas; on the northern side, Coffee plantations and the ruthless axes of the Corrumbur squatters have defaced what was, when we first knew it some forty years ago, one unbroken line of Forest; not that a Coffee plantation in full leaf is not a pretty sight of itself, still it cannot be compared with the grandeur of a primeval forest.

On entering the garden, we find ourselves amongst spice trees of various kinds, all growing with great luxuriance. The Nutmeg with its lovely cream-colored fruit reminds one, of choice white nectarines. The Mangosteen, a tree of a most beautiful habit of growth, of a symetrical pyramidal habit, the Clove, the Pimento or all spice, the Cinnamon; then we have the Leechee, the Orange, the Pommelo and Bread fruit. West African Coffee, Liberian and Mocha; the Ipecacuanha, the Cocoa, the Bullock Heart, Custard Apple, Plantains, Vanilla, Pomegranate, etc. Of the Mangosteen, we found there were some twenty-five plants in the garden, from five to thirty years of age. The tree first begins to bear at twelve years; we learnt that it was very difficult to raise the seedlings, that they had a habit of dying out when about one year old: we asked if grafting on the jungle garcinia * had been tried, and were surprised to find that it had never been tried; as it is desirable that this queen of fruit trees

* The hint might be taken in Ceylon as well as in India.—ED.

should be propagated largely, we would strongly advise the Director to turn his attention to the grafting, inarching and budding of the garciuias found growing wild from three to five thousand feet in the valley; there should be no difficulty in transplanting trees of ten years of age into the gardens, and then fruit would be produced in from two to there years. Fortunately, the same difficulty does not occur in propagating that very delicious fruit the Leechee which grows readily from seed, and we are surprised that this valuable fruit is not more widely known and appreciated. We believe it could grow readily up to five thousand feet elevation, provided frost was kept from it. The Chinese esteem the fruit highly, and it has been largely cultivated in Bengal. It might be grafted on *Sthleichera trijuga* which is a common tree in the Wynaad and of the same sapindaceous order. The orange trees in the garden did not look healthy; we consider they are suffering from want of manure, they are mere twiggy bushes in comparison with that noble tree in Gray's Garden at Coonoor, which is said to bear three hundred dozen of splendid oranges and to consume fifty loads of manure annually. Whilst on the subject of oranges, it may be as well to note that the celebrated orange gardens of hundreds of acres near Sydney, in Australia, are heavily manured with bone dust, whereby their flavor and bearing properties are largely increased. The Pommelo trees also looked mean, probably suffering from the same cause. There is said to be a very superior variety of Pommelo grown near Rajahmundry.

We were disappointed in the Vanilla plant: no attempt at growing it successfully seemed to have been made. We have heard that a Frenchman near Mahe has grown it very successfully; he has his plants in a walled garden trained over a trellis like a vine, for the roots he uses charcoal, broken bricks, and much manure.

We were disappointed to find the following valuable plants missing, they should certainly be introduced speedily, and, we think the Director might apply to Government for a special grant on this head. We know of no country where fruit is more required than in the Madras Presidency, and where there is so little fruit fit to eat. The coffee planter would find the growing of a few fruit trees, not only a profitable, but pleasant occupation for his leisure hours. In our market here, we can obtain a few kinds, mostly inferior, such as oranges, jak, plantains, and that is about all. The price of Mangosteen fruits at Burliar is three rupees a dozen; this is almost prohibitory, as the fruit is so small that on a hot day one could easily eat ten rupees worth, and (and like the man who eat six kittywakes as a whet to his appetite before diuner) feel no hungrier than when he commenced; certainly they would not be equal to half a dozen graft mangoes, which in the season can be bought for a rupee. There is a bread fruit tree in the garden, but the produce is inferior and full of seeds. The best sorts come from the Marquesas Group. If once a market was found for really good fruit at a moderate price, we are sure fruit cultivation would be carried out largely; at present, there is no market and there is no fruit As for Bangalore, the fruit, like the vegetables there, has no flavor, strawberries are insipid, apples are woolley, figs have no flavor, grapes ditto.

We would recommend the Director to obtain the following fruit trees as soon as possible, and no doubt, when people have tasted really good fruit, sold at a moderate price, the demand for such will be considerable. Vines from Arungabad: the Hubshee grape is noted for its fine flavor, also the best kinds from the Cape, Australia and from England. Those growing in a cool virery as well as those in a stove house, also the celebrated Catawba vine from America, and some from California.

Figs; all the best varieties from England and Italy.

Orange; the best varieties.

Pommelo or Shaddock: the best varieties.

Peaches: those from Candahar, Quetta, &c., might thrive well, say in a Coonoor climate.

Plums: varieties.

Graft Mangoes; there are some very fine kinds to be got from Goa.

Pine apples from England.

Cucumbers could be grown for fruit and seed at Burliar, the best sorts should be got out from home, such as Telegraph.

Melons: the same remark applies.

Mulberries, Avacado pear, Sour sop, Diospyros Kaki from China, Rambutan from the Straits.

Edible Passion fruit.

Then again there is the Hya Hya or cow-tree; Tabernæmonta a most valuable tree.

Paullinia Sorbilis or guarana; for the bread made from the seeds; very nourishing.

Then we might have cardamoms, pepper, ginger, turmeric, sweet and bitter cassava, the large capsicum that grows in Egypt. Tomatoes, coca which now grows in the Museum gardens at Madras, from this plant Coacine is made, which promises to be of immense importance in surgical operations.

We have drawn up but a short list of what might be successfully tried in the Burliar Gardens, and we trust, as our Director of Parks and Gardens on the Neilgherries has so high an opinion of the capabilities of Burliar, that he will not fail to avail himself of them. If he only introduces the few trees that we have named, he will have has work cut out for years to come, and with a stall in our grand new market now building, he cannot fail to find the undertaking, both remunerative to Government and a stimulus to private enterprise. With our changing population, it is useless to hope that private individuals will inaugurate experiments such as we have indicated; they have neither the knowledge, the money, nor the time. It remains for the Government to do what private individuals cannot or will not do; and, as this lies in Mr. Grant Duff's peculiar line, we commend our remarks to his notice, and trust he will give a hearty support to the Government Director. We have, in a former article on fruit growing on these Hills, alluded to the little progress that has been made hitherto, but we trust all such perfunctory modes of doing work on these Hills as have hitherto prevailed, will be numbered with the things of the past, and a new order of things arise, which shall really be a benefit to the country generally.—*Planters' Review.*

SELF-SUPPORTING EMPLOYMENT FOR LADIES IN THE SOUTHERN STATES OF AMERICA.

A PRIZE ESSAY.

Marriage, however desirable for a woman—and according to God's law it is the most happy and natural destiny she can look forward to—ought not to be her one aim in life: for the manifest reason that all women cannot, in the nature of things, attain that end.

The *Culture of Flowers* is an almost universal occupation with us, both in town and country. In our genial climate flowers grow to the greatest perfection with the least possible care. Now consider the thousands of dollars spent daily in our large cities for floral decorations. There is scarcely a social occasion on which floral designs are not in demand, and we all know the extravagance of the demand at funerals. At present they are made almost exclusively by men—professional florists. This work is natural to woman. Her fertile brain can invent designs which her deft fingers can swiftly execute. Gardening in all its branches has received much attention from English gentle-women, as witness Jane Chesney's "New Vocation for Women" (in Macmillon's Mag. Vol. 40.) In France and Switzerland it is made a branch of education for girls, as well as boys. Except the important work of preparing the soil, there is but little hard work. Many have done it for pastime, why not others for profit? The growth of flowers for seeds requires less capital and is perhaps commercially more profitable than when the production of the flowers themselves is aimed at. It is well to pay special attention to such plants as one is particularly successful with. Take for instance the old fashioned mignonette, heliotrope, asters, &c.; new varieties are always in demand and bring good prices. The beautiful orchids, palms, ferns, and foliage plants which seem to grow under the fostering care of some amateur gardeners as if for the very love of growing, bring immense prices in the large cities, while the homeliest old-time balsams, sun-flowers, dahlias, pansies, &c., are perfected and cultivated to such a degree as to be commercially of considerable value.

To horticulture it is essay to add *Fruit Culture*: 2. The orchard is not outside of woman's domain. Grafting and budding; selecting and packing the ripened fruit, who could better accomplish this kind of work? In these pursuits especially I would say, work upon the principle of doing the very best that can be done. Raise the choicest fruits and flowers; select them carefully and offer them for sale in the most attractive style. It will pay you to have your rosy-cheeked apples, luscious grapes, plums, peaches and pears free from dust, and packed with neatness and care.

3. *Silk Culture* which has been receiving much attention of late years, is a growing industry which Southern ladies will do well to look into. Mr. Crozier of Corinth, Mississippi, spent eight years in visiting Asia Minor, Syria, Turkey, Wallachia, Persia and Japan in search of the best breeds of silk worms. He seems to have made an exhaustive study of the subject; and after ten years, experience in Missouri, Kansas, North Carolinia, Lousiana and Mississippi, concluded that none of the silk growing countries he visited were better adapted to silk culture than the Southern and Middle States. The Corinth Mississippi Silk Co. offered, in 1882, 1,000 eggs for $1.00 and mulberry trees a year old for $1,000 per hundred. They offered also to pay cash at Lyons prices for all good cocoons. The Woman's Silk Culture Association at Philadelphia makes the same offer, and will pay for cocoous according to the market value of the silk obtained from them. Late experiments have shown that the osage orange, of which we have an inexhaustible supply in the South, is better food for the worms than the mulbery. Of course it is impossible within the limits of an essay like this to go into any details of methods of such occupations as are discussed: but those interested who wish to take up silk culture for instance can obtain circulars of information from the Woman's Silk Culture Association of California. It is an occupation of exceeding interest, and has the great advantage of not requiring a large outlay of money.

4. *Poultry Raising*, even without any of the new patent incubators, can be made vastly profitable by the sale of eggs alone: nor need this industry be confined to country people, though of course poultry can be raised at less expense on a farm than in town. A judicious selection of good breeds of fowl, careful pains taking, attention to the henery, which by the way should not be over-crowded, is almost sure to repay amply the outlay in the beginniog, which may be very small; and eventually to yield a good profit. In this, as in all other pursuits, concenteration of energy is the prime factor of sucess.

Leaving the domain ot garden and field, let us see what can be done with the kitchen fire. Next to the cultivation of flowers, Southern women excel perhaps in the (5) *Creation of Table Delicacies*. Many well-to-do families in cities would be glad to purchase at good prices, such home-made delicacies as would yield a handsome profit to the producer. Notwithstanding this day of canned goods, there are some things to be desired that are not found in canneries. The old-fashioned preserves, marmalades, jellies, sweet pickles, &c., that in our childhood were the delight of our hearts, and the pride of our grandmothers, have almost disappeared from our tables, and their places are supplied with canned horrors. A despairing writer in Harper's Magazine sometime ago asked, "Where, with the fullest of purses, can one buy quince marmalade?" Thousands of families live upon baker's bread who would gladly pay the same prices for a good article of home-made bread if they could be regularly supplied with it. The profit on bread is enormous. So with cake and pastry. A lady in Maryland finds ready sale for spiced beef at thirty cents per pound, the profit on which is fully 100 per cent. What is needed is the regular systematic production of such desirable articles as house-keepers need, and a ready market can easily be found. The grocer from whom supplies of flour, sugar &c., are bought would in most instances take such products as are sale, able on commission. Here again I would caution the novice against attempting too much.

If you are a first rate bread maker, stick to bread making—don't scatter your energies. Have regularly at your place of deposit a fresh supply; and have an order-book always ready for your customers when special supplies are needed. Let your aim be to produce a *superior* article; remember that you cannot compete with bakers and canners; but you may certainly produce what they cannot; a wholesome and toothsome article of food; and if offered at a fair price, it will bring you a good return.

So far I have spoken only of a few pursuits, to which Southern women seem best adapted; and which seemed to the writer the most practical. But there are higher vocations and professions waiting. These call for training and study. The best years of the girl's life must be given to hard work in class-room, the lecture-room, the laboratory or the dissecting room if she is to follow in after years any of the higher professions. These years of toil, days and nights of study are the only "sesame" that shall open for her the gates that guard the treasures of knowledge. Work, earnest, loving work alone will lead to success.

6. *Positions* of *Trust* are open to women when they show themselves fitted to fill them. Any women of average ability can, with practice, become a good accountant. Book-keeping is by no means beyond her powers. Recent disclosures of fraud, and embezzlement of funds by defaulting clerks, point to a fair opening for women. She has less temptation to dishonesty than man has; why should she not put herself in trainiog for such work? A druggist of many years' experience said to the writer that it was almost impossible to obtain a reliable clerk for his business. The temptation and opportunities to drink are so great. What more beautiful or interesting study than that of ehemistry!

7. The compounding of prescriptions, as well as manufacture of the various preparations, tinctures, extracts, syrups, &c., in constant use in every drug store, is work well adapted to women. The same may be said of telegraphy and type writing.

One might fill volumes with the enumeration of the various occupations and trades that are open to women: but the vital question is, for each individual woman, "What is *my* special vocation?" "For what are *my* powers, mental or physical, best fitted?" Not "what is most lady-like or fashionable, or least open to social criticism;" but "what can I do *best*, and what is most profitable to soul and—purse." A true woman can ennoble the meanest drudgery. It is the spirit and mind of the worker, the truthful earnestness of purpose, the honest intentions, the faithful performance of duty, that gives character to toil. And if a woman is to engage in any self-supporting employment she must make toil her daily companion and friend. The markets that are calling for your fruits and flowers; the looms that are ready for your cocoons; the hungry public that are ready to buy your delicious bread and jellies or dainty cakes and pies, are impatient; and will not wait while you dawdle. If your supplies are not prompt, they will buy elsewhere.

The woman's cry need no longer be "stitch, stitch, stitch!" The "Song of the Shirt" is now a thing of the past, but the refrain is only changed to "work, work, work!" The curse of Eden is still upon us. Not man only must live by the sweat of the brow; but it rests with woman, perhaps, to transform the curse into a blessing.

Make choice of the fittest calling, pursue it earnestly. As earnestly as if it were the one thing in life worth living for; know it thoroughly, though you know nought else. As a toiler and bread-winner, banish from your mind the long cherished notion of the ideal woman. A creature to be flattered and caressed; to be shielded from the storm and blast, and sheltered always by man's protecting arm; for in this work-a-day world the real and the ideal are as far removed from each other as the heavens from the earth.—JEAN BAYLY.—*Southern Planter.*

BLIGHT.

In our last issue we referred to the publication of a work by Mr. Wood-Mason, on the subject of Tea Blights. The only two blights touched upon, however, are the Tea Bug, or Mosquito blight, and the Tea Mite, or Red Spider. Formidable, undoubtedly, as these pests are, there

are so many other forms of blight, almost equally destructive, that it is to be regretted Mr. Wood-Mason's researches were limited to the two mentioned.

Some years ago we collected a large variety of opinions and remarks on the subject of "Blight"—specifying the many different forms of blight to which the tea plant was liable. As we then remarked:—"There is perhaps no subject of more serious importance to the tea planter than that of "blight." Come in whatever form it may, it means very often the ruin of his hopes, and the extent of the money lost which the Industry has suffered in the past few years from red spider and other pests renders it a matter of astonishment that proprietors have been content to sit down quietly under the infliction instead of long ere this having organized a searching and thorough scientific investigation into the evil." As we say, then, it is to be regretted that Mr. Wood-Mason's researches were limited to only two varieties. But as this is so, it may not be uninstructive to reproduce certain of the opinions given, and information obtained, at the time we first took up the subject. Planters may, by the light of more recent experience, be now able to furnish additional facts and the results of more recent experiments essayed in the way of remedy against the evil which still exists in all its force. We have not only the Tea Bug and the Red Spider committing their ravages, but there is Blister-blight, Caterpillar, Borer, Orange Beetle, Green Fly, and other varieties of pests almost equally worthy of notice as the Tea Bug and the Tea Mite. Why Mr. Wood-Mason should have confined his attention to the two latter only, we do not know. Probably the time at his disposal was insufficient to enable him to inquire regarding other than the two forms of blight he has selected. Still, it is manifest that the subject of Tea Blights has only very partially been dealt with in way of "investigation," and the necessity still exists for much further and more comprehensive enquiry. We trust, therefore, that those of our readers who may have made any recent special study of the subject of Blights as affecting the tea plant will supplement the information, which at present only to a very limited extent exists, in regad to possible remedies against Tea pests. The least harmful of these, Mr. S. E. Peal states, is perhaps the caterpillar, and from its size it is more readily seen, being from 2 to 2½ inches long. It attacks the foliage only. Children, on some estates, are employed to "weed" this blight, and on a garden at Hope Town we saw several casks full of caterpillars which had been brought in by little nimble "pluckers," in baskets—the payment being so much for each basketful. Half a maund of caterpillars a day can, it is said, be collected by five or six children. If the caterpillar is, as Mr. Peal says, the least harmful of all, it can only be in the sense that it can be readily detected, for it will completely strip a bush in a short time, leaving only the stems. There is another variety of caterpillar —the Borer. This attacks the stem, and "is generally not seen till some damage has been done," which consists of "the leaves drooping" turning red, and dying." It thus causes more real damage than caterpillar. The only known remedy for this pest is discovery and destruction. Children can in this case also be employed, as a hole is always detected, from which it works upwards or downwards.

Another pest, *Orange beetle*, though an insect feeding on grass and on other plants besides tea, is a formidable tea pest, as, says Mr. Peal, the insect may ruin half a dozen shoots as one morning's work. As these beetles fly, and are easily caught, boys with butterfly nets can keep down the evil a good deal. Mr. Peal says: "A boy can easily bag 300 beetles per hour if they be at all plentiful, and the net need not be emptied till 20 or so are caught."

Then we come to the *Tea Aphis*, which is a serious enemy to the tea plant indeed. The female lays 600 or 700 eggs in the cracks of the bark, says Mr Peal. These eggs are hatched in the ensuing spring, "and in 8 or 10 days are full grown; and at once, without the intervention of a male, begin to lay, not eggs, but hosts of young *Aphis* ready hatched, each of which in 8 or 10 days again repeats the above." The *Aphis* "is from ⅛th to ¼th of an inch long, and of a glistening pale green color. In attacking tea, the young leaves and stem alone are punctured, growth becomes remarkably arrested, the internodes or stems between the eyes become shortened, and the leaves present a pale and dwarfed appearance."

Then we have the cricket, which is so common and destructive in Cachar. A correspondent thus describes it:—This insect is about 1¼ inch in length when full growo, and lives in small burrows, sometimes singly, sometimes two or three in one hole. The burrows frequently penetrate to a great depth, and where the crickets are so numerous that it becomes necessary to dig them out (which sometimes happens), the tunnels are followed a foot and a half or two feet, and even then not uncommonly without avail. The cricket feeds on the young leaves of the young plants; and to obtain these he cuts through the stem of the plant about three-quarters of an inch from the ground, and then carries off the top to his hole, so that each meal which the insect makes causes a vacancy; and where they appear in any number, the destruction may be imagined. They will cut through a stem as thick as a pencil without difficulty, and amongst small plants in a nursey they sometimes do incalculable mischief. I have seen them attack an old garden, where they ate off the young shoots, and thus did a great deal of harm to the succeeding flushes; but I have only once seen this occur.

Then again, there is the "grub," which at certain elevations is to be found in thousands. It is the progeny of beetles. It will desert the tea bush, however, for rotting vegetation, so may be readily caught.

Then there is the "blister blight," exactly as though a red-hot iron had been placed close to the leaf, and scorched it black. But, says a "Darjeeling Planter":—One of the worst pests is a very small black fly less than half the size of a pipsa, which attacks the stalk of the young flush and retards its growth wonderfully, giving the tree something of the look of a bhanji flush. There is no doubt that most of these blights are brought up every year, more or less, by the winds from the plains and the Terai. The rain at the commencement of this season did not allow of the usual burning of jungle to the extent of former years, and the rains since have been very slight;—no heavy downpours which would have drowned most of these small insects called blight; so that they have increased and multiplied, and become perfect pests. I have large forest trees both in my house garden and outside, and also toon and other trees in the forest, completely denuded of leaf by small invisible insects. These cannot have been deteriorated by over-plucking, since rose and other garden-plants and peach and filbert trees are also suffering in the same manner,—while the willow, pear, fir, and other trees are not as yet touched. Fumigation drives away for a time the mosquito and the other smaller insects that have wings, but only to settle in other trees a little further off; it does not kill them. Watering with salt water (a weak solution) drives them out grandly for a time, but they come back again.

The salt, if a weak solution, does not hurt the leaf, but helps to strengthen the root, as it must eventually be washed there by the action of the rain. I have in healthy seasons sprinkled salt on the ground at the root of the plant, and it has had a very good effect in lengthening the flush. The salt was given at the rate of 2 maunds per acre for each application and given four times during the plucking season. I would recommend it as one of the means of hardening and strengthening the plant, without detriorating the flush. I was recommended to water my trees with lime water, but considering that to carry the water would be a great trouble and expense, I commenced to dust the plants with lime, leaving it to the clouds to furnish the water. From dusting lightly I changed to dusting heavily. I noticed that the light dusting did not appear to hurt the plants; therefore I plucked clean, and dusted with lime heavily. This appears to have driven away every insect clean out of the tea trees. It is yet to be seen whether it will improve or spoil the next flush. Trees sheltered from the wind from the plains appear as yet to have escaped the various blights.

One can scarcely believe how harmful are the attacks of these small insects. The coolies of this part of the world (pahariahs) all wear trousers, which plainsmen despise. Having to clear a little piece of ground in my garden, and wishing to do it before evening, I called a plainsman to assist: he only wore a *dhotee*, and, consequently, was soon slapping his legs, on account of the pipsas, to the great amusement of the pahariahs. These pipsas also attacked my hands, and produced very great irritation. I can quite believe that some of the tea trees are almost, one might say, stung to death. Any one fresh from England, smarting from mosquito bites, can readily believe this. We cannot understand that jungle has any advantages; but I believe it has one,—than of being food for insects. It is well known that when grass is destroyed, then the grubs begin to attack the roots of the tea plant. One can scarcely understand that such a bitter shrub should be naturally sought for by insects. Indigo and tobacco are, I believe, also eaten, when green, by caterpillars, and if they have not their natural food, they will eat anything else that they can get hold of. Flies like tea in the tea-cup; they may be attracted by the sugar and milk, but it is death to them.

It will be seen from what we have mentioned, how much more inquiry and experiments remains to be conducted than are found referred to in Mr. Wood-Mason's book. The subject of Tea blights and pests is so important that, we trust, inquiry will not stop at its present point. The Tea Industry is large enough and rich enough to employ a special expert, to make every possible research, and we trust that the Indian Tea Association will see its way to considering the employment of such a specialist to go thoroughly into the matter of "Blights," and complete the work which Mr. Wood-Mason has begun. We shall return to the subject in a future issue.—*Indian Tea Gazette.*

THE TILLAGE OF THE SOIL

constitutes one of the most essential elements in the successful germination and cultivation of young plants, and the gardener who sows his small seeds in an imperfectly pulverised soil is only throwing away time and money.

The influence of soil upon the quantity of seed necessary to be sown is accounted for by the fact that in rich garden mould more or stronger stems will be thrown up faom each plant-root than if the soil be poor. To make up for this deficiency, and also to enable the crop more thoroughly to search for food, a greater number of plants is necessary, and a large allowance of seed is the consequence.

The depth most desirable for the germination of seed depends to a very great extent upon the closeness and adhesive character of the soil; the seed should be planted in that position which will secure to it such a supply of moisture, warmth, and air as will most rapidly promote healthy germination. It is clear that these conditions cannot be secured in soils of different texture at one uniform depth, and that this can only be safely decided by local experience.

The lighter and more loamy the soil the gardener has to deal with, the more important he will find it to sow his seeds at a considerable depth, as this not only favours the stability of the plant, but enable the small root-fibrils to obtain their necessary supply of moisture; the stronger and more clayey the soil, the greater the necessity for keeping near the surface.

In clay soils seed should be sown as a rule whilst the land is as dry as possible; it will be sure to receive moisture from the fall of rain; but wetness in adhesive soils causes the particles to bind together to the prejudice of the crop. As the soils we have to cultivate assume a large texture, there is less objection to working them when wet; in some cases, indeed, this even becomes essential in order to give the soil the required firmness, and the seed a sufficiency of moisture.

When a proper degree of tilth has been obtained and the seed sown, the introduction of atmospheric air beneath the surface of the soil by means of hand-hoe and similar implements cannot be too frequent. For as the majority of garden outdoor seeds are sown in early spring, their growth takes place at a time of year which is not only very favourable for active nitrification of the soil, but the soil is also less exposed to the loss of the soluble nitric acid by excess of rain.

Seeds sown in the spring and early summer have still one other advantage: nitric acid contains an immense amount of oxygen, and as it is only those particles of carbon which are close to the surface of the soil that can have access to oxygen, the constant stirring which a soil should receive during the early growth of plants is doubtless the means of continually exposing fresh surface to the action of atmospheric air, and so providing the young plants with food easily to be assimilated. Sir J. B. Lawes says, in an article on the "Action of Manures," he has more faith in these several causes being sufficient to explain the reason why mineral manure, or even phosphate of lime alone, is able to grow large crops of roots without a direct supply of nitrogen in manure—than he has in the explanation sometimes put forward, that plants with large leaves take their nitrogen from the atmosphere. —*Gardeners' Chronicle.*

THE COST OF A DEMERARA SUGAR ESTATE.

(*From the Demerara "Argosy."*)

SIR.—I see the *Produce Markets' Review*, of December 6, wishes for information concerning capital invested in a Demerara estate. Below is an estimate of the cost of one to make 1,000 hhds. or 900 tons of Sugar per annum. What such an estate could be purchased for just now would be certainly much less. The generally accepted selling price of a Demerara estate, viz., "One year's gross crop value," would make it about 80,000 dollars, but proprietors are hardly yet reduced to sell at such a figure. The *P. M. R.*, in comparing cost of production in Demerara and Barbados, puts the profits, on a 1,000-ton estate in the latter place, at £2,500. He cannot be aware that a 1,000-ton estate in Barbados would cost £100,000 at least; and that, until this past year, it would have given its proprietor £10,000 to £15,000 per annum. It is this land value which causes the distress amongst the proprietary body there. Most estates are owned by families whose capital is invested in them at interest. With present prices and present system of manufacture, the Sugar pays the cost of production and leaves a small surplus, but quite insufficient to pay the interest on the capital, which is usually about £5 per hogshead. By erecting Central Factories, with improved machinery, the Barbadians will obtain 10 per cent of Sugar from the Canes instead of 5 per cent as at present, and the price of land may then remain at nearly £100 per acre. If the present system be continued, the existing proprietors will have to live on their properties, and out of them, or let them go out of their possession.

The *P. M. R.* appears to think that the Sugar made into rum could be retained as Sugar. This may be possible in the future, but at present we cannot manufacture Sugar without debasing at least 40 per cent of the weight recovered. As to the charges imposed upon the Sugar hhd. from the time it leaves the estate, until it reaches the consumer, there is a good deal of mystery in their nature. To the uninitiated 1s. 6d. per cwt. freight, 3d. insurance, and 3d. commissions, dock charges, &c., would appear to be sufficient, as £2 per ton appear to pay very well for outward cargoes, even if the vessel returns with ballast; but when items such as primage, effecting insurance, del credere, brokerage, discount, &c., creep in, the total charges per cwt. mount up sometimes to 4s. About a year or more ago there was a correspondence in the *P. M. R.* about these charges, which was never satisfactorily concluded. Perhaps the editor will publish a clear account of the various charges necessarily incurred by one cwt. Sugar in transit from the estate to the buyer. Then one of your correspondents will give the actual charges, and some expert will explain to the unlearned what they mean, who gets the money, and what he gets it for.—I am, Sir, your obedient Servant, C.

COST OF DEMERARA ESTATE OF 1,000 HHDS.

	Dollars.
Purchase 750 acres land at $10	7,500
Cultivating 500 acres till reaping begins, at $100	50,000
Buildings to make 50 tons per week at £30 per ton	72,000
Dwellings for 500 labourers, 200 rooms at $100	20,000
Hospital	8,000
Managers' and Overseers' Dwellings	13,000
Stock...	2,000
Punts for Canes $8,000. Do. Shipping $3,000	11,000
Immigration expenses first year	6,000
Sluices, kokers, for drainage and water supply	10,000
Contingencies 10 per cent on $199,500 ...	19,950
	$219,450

To the Editor, Argosy.

*** The current charges for bag Sugars consigned to Merchants in the old way, and on the basis of a price of 15s. per cwt. should work out as follows:—

	s.	d.
Freight per Royal Mail Steam...	1	4½
London wharf charges, with one month's rent	0	3½
Marine Insurance (R. M. S. all the year, 12s. 6d. per cent.)	0	1½
Fire Insurance in London, at 6s. per cent per ann.		
Brokerage at ½ per cent	0	1
London public sale charges	0	0½
Merchants' Commission at 2½ per cent ...	0	4½
	2	3½

The charges for hogsheads come to more, and the housing and other charges at the docks are considerably higher, both for hogsheads and bags, than those given above, after allowing for the "discount" of 1s. 6d. per ton. The dock charges, however, cover two months' rent, and the fire insurance costs less there. Primage and effecting insurance appear quite unnecessary charges; and as no credit is given in the London market, no del credere ought to be debited to the planter. "C," in his original letter (quoted at length in the *P. M. R.* for the 29th November, 1884, and remarked on in the issue of the 6th December), does not appear to have allowed enough for dock and other charges here by about 9½d. per cwt. This would bring up his estimate of the landed cost in London, including all charges, of Demerara Sugar to 15s. 7½d. per cwt. Interest at 5 per cent on the cost of the estate given above would be 2s. 9d. per cwt. which can be included or not according to the views of the calculator on such points. If the Planters extracted the saccharine from their Molasses as the Germans do, there would be no Rum, but the more valuable Sugar instead. —ED. *P. M. R.*

COCA: ITS SOURCE, CULTURE, USES, &c.

The following is the lecture delivered by Dr. Bidie, M.D., C.I.E., in Madrars on the 28th March:—

The subject of my lecture tonight is Coca, which, owing to certain medicinal and other properties that it has been found to possess, is likely to become of very great importance as a commerical product, and as a therapeutical agent both in Surgery and Medicine. The substance known as Coca consists of the dried leaves of a South American plant, known to botanists as *Erythroxylon Coca*. In Southern India we have a species which somewhat resembles the American one, *viz. E. monogynum*,* common in Cuddapah and various other dry districts, where it is known as *Devadaru* and *Adavi goranta*. A curious thing happened during the famine with reference to the *Devadaru*. In Cuddapah the starving people were found to be eating considerable quantities of the leaves of a shrub, some of which were sent to me for indentification. Judging from their appearance, the leaves, which were rather dry and fibrous, did not seem likely to afford any nourishment, nor had they any special taste or flavour to commend them as a relish or condiment. They were found to belong to a species, of the same genus as the South American Coca, and it at once occurred to me that, like it, they probably possessed the property of allaying hunger and staving off fatigue. No chemical examination has, so far as I know, been made of the leaves of the *Devadaru* eaten by the famine-stricken people, but it is a curious coincidence that they should have been so used, and further enquiry may reveal that the Madras species contains some active principle allied to, or identical with, that of the American plant.

* Formerly called Sethia indica, D. C.

BOTANY.

According to Decandolle ("Origin of Cultivated Plants," p. 136,) *Erythroxylon Coca*, Lam. is a native of the east of Peru and Bolivia. It belongs to the tribe *Erythroxyleæ* of the order *Linaceæ* or Flax family, and its specific appellation, Coca, is supposed to be derived from the native name, *khoka* or *tree*, that is the tree *par excellence* (Markham's "Travels in Peru and India," p. 235.) It is now some time since the plant was introduced into this Presidency direct from Kew, and also by Mr. Cross, when he paid his last visit to the Nilgiris, entrusted with some new species of Cinchona. As seen here, and also in its native country, Coca is a bushy shrub, with numerous smooth leaves of a beautiful golden green colour above, and paler and glaucous on the under surface. The leaves are lanceolate or somewhat oval in shape, and trapering at the base towards the leaf stalk. At the upper end they are blunt and emarginate with, when young, a little prickle-like process in the middle of the notch. The characteristic marks of the leaf are two arched raised lines on the back, which extend from the base to the apex—one on each side of the midrib—and enclose a space which is somewhat hollow and paler in colour than the rest of the surface. The flowers are small on slender drooping stalks, and of a yellowish colour. The fruit is a pretty little drupe over one-fourth inch in length, of oblong ovoid shape, quite plump when green, but furrowed longitudinally when dry. It takes from a fortnight to three weeks to germinate in Madras, and is easily raised in pans containing a mixture of leaf mould and sand.

DISTRIBUTION.

Coca is cultivated to a very large extent in Peru, Bolivia and Columbia, and also in parts of Brazil, the Argentine States and other countries of South America. It is said to thrive best in the moist mild climate, which exists at an elevation of from 2,000 to 5,000 feet above sea-level in the warm moist valleys of the eastern slopes of the Andes of Peru (Bentley and Trimen's "Medicinal Plants," No. 40). The Coca plant in this Presidency thrives very well at sea-level on the Coast, but its culture will probably be found much easier and more successful at higher elevations, say, from 1,500 to 6,000 feet.

HISTORY.

The commerical product known as Coca, cousists of the dried leaves, which are used as a masticatory by the Peruvian Indians to give comfort and enjoyment just as the betel leaf is chewed in India. From time immemorial the inhabitants of countries on the Pacific side of America have used this leaf, and, according to Markham, the Peruvians still look upon it "with feelings of superstitious veneration." In the time of the Incas, the former rulers of the country, it was employed in sun-worship, and also in barter instead of money. After the Spanish conquest, some fanatical invaders proposed to prescribe its use and stop its culture, on the grounds that it fostered ancient superstitions and took away the Indians from other work. In 1569 the second council of Lima condemned its use, because it was "a useless and pernicious leaf, and on account of the belief, stated to be entertained by the Indians, that the habit of chewing Coca gave them strength, which is an illusion of the devil" (Cedula, quoted by Markham in his "Travels in Peru and India," p. 232). About the same time the Spanish Government interfered with the cultivation, on account of the unhealthiness of the valleys in which the "Cocales" or plantations were situated. Subsequently, between 1570 and 1574, the Viceroy, Don Francisco Toledo, endeavoured, by various edicts, to regulate the industry, so as to protect the health of the Indian labourers, and to ensure their being properly paid. According to Bentley and Trimen ("Medicinal Plants,"

No. 40,) the total annual produce of Coca in South America at the present day is probably not less than 40,000,000 lb., which, estimating the value on an average at the low price of 1s. per lb., gives a total of £2,000,000 sterling. The great virtues ascribed to Coca have from time to time attracted the attention of travellers, physicians and chemists, but until quite lately its merits have in Europe been considered somewhat hypothetical. Now that the value of its alkaloid, as a medicinal agent, has been fully established, we may expect that further uses for it will be found, and that a demand for it will arise throughout the civilised world.

MODE OF CULTURE IN SOUTH AMERICA.

The Coca plant in Peru is raised from seed sown in a small nursery, generally protected from the direct rays of the sun by a thatched roof or rows of maize. Sowing commences in December and January, when the rains begin. After sowing, the seeds require to be regularly watered, and may be expected to come up in from two to three weeks. In the following year, when from 1½ to 2 feet high, they are transplanted to prepared ground in the plantation, generally in terraces, where they are placed in square holes about a foot deep, and with the sides supported by stones to keep the soil from falling in. Three or four are planted in each hole and allowed to grow up together. In level ground they are planted in furrows separated by walls of earth, at the foot of each of which a row of plants is placed. The usual distance apart is eighteen inches each way; and the culture extends up the steep sides of the valleys, as high as 8,000 feet where the mean temperature is 64° 68° Fhr. "At the end of eighteen months the plants yield their first harvest and continue to yield for upwards of forty years" (Markham's "Travels in Peru and India," p. 235). The plants require to be very carefully weeded, and if the rains are favorable, three crops of leaves may be expected every year. The produce of an acre is estimated by Weddell at about 900 lb. in a favorable season, but the average is doubtless less. The leaves should not be gathered till mature, at which time they are bright-green on the upper, yellowish-green on the under, surface, break off easily when bent, and have an agreeable somewhat fragrant smell. They must be collected separately and carefully, so as not to injure the buds that produce the following crop, and to prevent their being torn or bruised, which would impair their commercial value. The harvest is greatest in a hot, moist situation, but the best flavoured leaves are said to come from plants growing in drier parts high up on the sides of the hills. The green leaves, when picked, are carried in cloths or baskets to the drying yard, where they are spread out on woolen cloths or on floors formed of slate-flags, and dried in the sun. Very great care requires to be exercised in the drying process, as, if dried too rapidly, they get shrivelled and brittle and lose their odour and green colour. On the other hand, if imperfectly dried, they get dark in colour and have a disagreeable odour and taste when packed. In small experiments here I have found it better to dry them on a table in an airy room, and not in the sun. In some districts it is said the leaves, while yet green, are trodden down with the feet, so as to give them a delicate flavour. This may have the effect of producing a mild sort of fermentation in leaves which have been bruised. Well-cured leaves are uncurled, of a fine green colour on the upper surface and greyish beneath. They have a tea-like odour and pleasant taste, and produce a sense of warmth when chewed. Badly-cured leaves are dark-coloured, less fragrant and devoid of the warm feeling when chewed. When dried, the leaves are either stored in houses or packed in sacks of cloth (*cestos*) lined with banana leaves, each of which weighs about 20 lb. The size of the packages varies in different districts from 20 to 150 lb. There can be no doubt that the Coca suffers in transit or when long stored in bags, and that it would be a great improvement to pack it in like tin, lead-lined chests, tea. Shuttleworth ("Pharmaceutical Journal," Vol. VIII. p. 222,) says that "in South America particular care is taken to procure the leaves in as fresh a state as possible, and many writers have ascribed the want of effect to the use of old leaves. I have no doubt but Coca deteriorates by age, as will also tea and most medicinal plants; but I am certain that it does not become wholly inert if preserved with care." Dr. Squibb ("Pharmaceutical Journal," No. 739 of 1884, p. 145,) observes: "Coca is well known to be a very sensitive and perishable drug," and again "very much like tea in this and other respects, it, should be packed and transported with the same care and pains, in leaded chests or in some equivalent package. It is very well known that tea, if managed, transported, handled and sold as Coca, it would be nearly or quite worthless, and therefore Coca, managed as the great mass of it is, must be nearly all of it comparatively worthless." If Coca grown in India is ever therefore to take an important place in the European market, it must be dried with great care, and packed so as to preserve its virtues. In South America not less than 8,000,000 of the inhabitants habitually chew the leaf, and deem it as much as necessary as the people of this country consider the betel-nut. As, until within the last few months, the consumption of Coca for medicinal and other purposes has been small, it is probable that it will be some time before the supply grown in America overtake the demand for it which has sprung up in Europe and elsewhere, owing to the wonderful anæsthetic action that the alkaloid made from it exercises, when applied to mucous membrane and other tissues of the body. This alkaloid, Cocaine, was recently sold in London at prices ranging from 2*s.* 6*d* to 4*s.* the grain, and when it is mentioned that the leaves do not on an average yield more than 0·2 per cent, it will be obvious that there is abundant room in the English market for additional importations of the leaf, and good prospects of liberal profits for the grower. It has also to be repeated that the leaf is very perishable. After being stored for five months in its native country, it is said to lose its flavour and to become worthless. Supplies of the fresh article will always therefore be in demand.

MODES OF USING THE COCA LEAF IN SOUTH AMERICA.

The Peruvian Indians masticate the Coca in combination with the alkaline ashes of the stalk of the quinoa plant (Chenopodium quinoatrs.) In other places, pulverised quicklime is used. In Brazil the leaves are first dried, and then reduced to powder in a wooden mortar along with the ashes of a plant. An Indian usually partakes of Coca three times a day, and consumes altogether about three ounces of the leaves daily. As it is chewed, it emits a grateful fragrance and promotes the flow of saliva; and according to Markham, "its properties are to enable a greater amount of fatigue to be borne with less nourishment, and to prevent the occurrence of difficulty of respiration in ascending steep mountain sides." It is also sometimes infused like tea, and the beverage drunk; and Mr. Holmes, of the Pharmaceutial Society's Museum, informs me that a nice liqueur is prepared from the fresh leaves in Bolivia. A fluid extract, prepared in South America from the fresh leaves, has for some time been imported into England.

PROPERTIES AND USES.

Coca has long been regarded as a stimulant of the nervous system and sustaining agent, and the poet Cowley who lived in the middle of the 17th century, puts the following words into the mouth of an Indian Chief who is addressing the heathen goddess Venus:—

"Our *Yariocha* first his *Coca* sent
Endow'd with leaves of wondrous nourishment,
Whose juice once'd in, and to the stomach ta'en
Long hunger and long labor can sustain;
From which our faint and weary bodies find
More succour, more they clear the drooping mind
Than can your *Bacchus* and your *Ceres* joined.
The *Quitoita* with this provision stor'd
Can pass the vast and cloudy *Andes* o'er."

My friend, Dr. Mantegazzo of Florence, who visited Madras a few years ago, on a scientific expedition, always carried a supply of Coca wherever he went. He became acquainted with it while resident in South America, and carefully investigated its properties. According to him, when taken in excessive doses it causes delirium, hallucinations, and ultimately congestion of the brain. In full doses it stimulates the heart and respiration and increases the temperature of the body. When

chewed, as the natives do, or given in weak infusion, it promotes digestion. In larger doses it stimulates the nervous system, so that muscular exertion is easily undertaken. Mantegazzo recommends its use in a variety of diseases. In 1876 Sir R. Christison, the veteran therapeutist, made some experiment with Coca on himself and students attending his class. From these he arrived at the conclusion that "the chewing of Coca removes extreme fatigue and prevents it. Hunger and thirst are suspended; but eventually appetite and digestion are unaffected. No injury whatever is sustained at the time or subsequently in occasional trials; but I can say nothing of what may or may not happen if it be used habitually. From 60 to 90 grains are sufficient for one trial; but some persons either require, more, or are constitutionally proof against its restorative action. It has no effect on the mental faculties so far as my own observations go, except liberating them from the dullness and drowsiness which follow great bodily fatigue. I do not yet know its effect on mental fatigue purely. As to the several functions it reduces the effect of severe protracted exercise in accelerating the pulse. It increases the saliva, which, however, may be no more than the effect of mastication. It does not diminish the perspiration so far as I can judge." About the same time that these results were obtained by the scientific observer in Edinburgh, a Mr. Dowdeswell, who had been experimenting with Coca in London, declared that the results of his investigations were negative. He says:—"Without asserting that it is positively inert, it it is concluded from these experiments that its actions is so slight as to preclude the idea of its having any value, either therapeutically or popularly." This testimony, being so utterly opposed to the experience of other competent observers, and to the fact that Coca has been chewed from time immemorial, and is still used by millions of people in its native country, can only be explained by the supposition that Mr. Dowdeswell did not get the genuine article, or it may have been old and inert. Quite recently a well-known London firm sent me a sample of what they called Coca, in order that I might become familiar with the commercial aspect of the drug as now sold at home; but, on examination, I found that it did not contain one leaf of *Erythroxylon Coca!* As already stated, Coca is a very perishable article, a fact which is sufficient to explain much of the contradictory evidence in existence regarding its refreshing and sustaining effect. A few years ago a number of men connected with the Toronto Lacrosse Club in Canada, resolved to try the sustaining effect of Coca in this game which involves violent bodily exertion. At the beginning of every match a dose, ranging from 1 to 1½ drs. of the leaves, was served out to each man, which was chewed gradually during the game. The trial extended over nearly a year and-a-half, and the majority of the experimenters were "strongly in favour of Coca—some most enthusiastically so—while two or three out of the number remained indifferent, having derived no direct or apparent advantage from its use (*Pharmaceutical Journal*, p. 222, vol. 8, 1877). This is only what might be expected, as tea, coffee and tobacco produce, owing to idiosyncrasy or difference in sensitiveness, very different effects both in quality and degree in different individuals. Quite recently Dr. Caudwell of Westminster Hospital, London, has been trying on himself the effects of large doses of oca. He first used the alkaloid (a fluid extract equivalent to its weight of the leaves), and increased the doses gradually from 2 drs. to 2 oz. The latter dose produced giddiness and unsteadiness of gait for about ten minutes, and then a general sensation of comfort with considerable mental excitement, and ability to read steadily for many hours, and to keep awake all night. He next tried the alkaloid Cocaine, increasing the amount from half a grain to 5 grains. The latter dose caused toxic symptoms, and produced dilatation of the pupils, which lasted for six hours (*Pharmaceutical Journal*, No. 762, third series, p. 613). So far as we know at present, Coca exerts a double action, being a cerebral sedative in small doses and a cerebral stimulant in large. But it is unnecessary to pursue this aspect of the subject further. The fact that 40 000,000 lb. of Coca are consumed annually by the inhabitants of South America, is itself suggestive and conclusive, and when to this are added the results of independent investigations and our recent knowledge of the alkaloid Cocaine, we can have no hesitation in accepting Coca as an article quite as useful to humanity as either tea or coffee, and destined, as far as present appearances go, to become infinitely more so.

THE ALKALOID COCA.

The existence of an alkaloid in the leaves of the Coca plant was suggested as early as 1853, by Wackenroder and Johnston, and in 1855 Dr. E. Gaedeke, a German, succeeded in isolating it, but not being able to satisfy himself as to its identity with *Theine*, the alkaloid of tea, he provisionally named it "*Erythroxyline*." But it was not till 1860 that the physical characters of the alkaloid were fully ascertained, and the honour of their description belong to Nieman, who called the substance "Cocaine." Somewhat later Lossen found in the leaves another base, which he termed "Hygrin," and which is volatile and apparently inert. The other chief constituents of Coca are *Ergonin*, *Cocatannin* and a peculiar *wax*. Cocaine crystallises in small colourless and inodorous prisms, which are slightly soluble in water, more so in alcohol, and very soluble in ether. It has a strong alkaline re-action, a slightly bitter taste, and produces upon the tongue a temporary but almost complete insensibility at the point of contact (*Pharmaceutical Journal*, No. 753, New Series, p. 421). An attempt has been made to change the designation of the alkaloid to *Cucaine*, but as that would be at variance with the botanical specific name, the alteration seems undesirable. The chemical formula for Cocaine is C-1-7, H-2-1, No. 4, so that it is very nearly allied in its composition to Atropine and Daturine. The most useful salts of Cocaine are the hydrochlorate, the citrate, and salicylate. At present the hydrochlorate is the favourite preparation. It is defined as a white crystalline powder of weakly acid re-action, with a somewhat bitter taste, and producing on the tongue a temporary characteristic insensibility. When heated upon platinum foil it should leave no residue, and it ought to dissolve in double its weight of cold water, and not become coloured in contact with mineral acids. It also dissolves easily in alcohol. Although the local anæsthetic properties of Cocaine were recognised so long ago as 1860, curious to say no practical use was, until quite recently, made of the discovery. This is all the more remarkable, inasmuch as Dr. Hughes Bennett, in 1874, found, in investigating the action of Cocaine on frogs and other animals, that it "exerted its influence on the sensory nerves, and that the nerve-endings in the skin and the mucous membranes were rendered inexcitable, apart from any action or influence on the nervous centres." The credit of the practical application of the anæsthetic properties of Cocaine belongs to Dr. Kollar, a young physician of Vienna. He suggested, in the course of last year, its application to the eye for producing temporary insensibility during operations on that most sensitive organ, and the momentous value of the discovery was at once recognized all over Europe and America. In fact ever since Cocaine has received an amount of attention which shows the high rank it is likely to attain as a therapeutical agent. Professor Knapp, who was one of the first to carry out experiments as to the effects of Cocaine on the eye, found that when a 4 per cent solution is applied, the pupil begins to dilate in from ten to twenty minutes, attains its maximum in from thirty to forty-five minutes, remains stationary for about half an hour, and then slowly diminishes. The reduction of sensibility begins in about three minutes after the application of the solution, increases from ten to twenty minutes, and is over in about half an hour. When applied in appropriate quantity to the eye, it completely obliterates sensation for the time being, and renders it absolutely insensible to pain, and it neither causes irritation, induces injurious re-action nor interferes with the vitality of the tissues. But it is not only in diseases of the eye that Cocaine is useful, as it acts equally on the mucous membrane of the mouth, pharynx, larynx, nose, trachea, &c. It also acts quickly through wounds or abraded surfaces, but is slowly absorbed by the skin. When injected hypodermically it acts efficiently as a nervine, in doses of half a grain. The dose internally of Cocaine

is from one-half to 2 grains, and, unless in large doses, it does not manifest any toxic action. In a popular lecture in this theatre it is not necessary, nor would it be appropriate, for me to say more as to the medicinal properties of this new remedy. Although its therapeutical value was discovered only a few months ago, its fame has already extended to the utmost bounds of civilization, and the only barriers to its extended use are its scarcity and costliness.

FURTHER POSSIBLE POPULAR USES OF COCA.

It is a very curious fact, that about three-fourths of the human race consume, as beverages or otherwise, five different articles, all of which have exactly the same active principle, viz., an akaloid called *Theine* which received its name from having been first discovered in tea. The substances referred to are tea, coffee, mate or Paraguay tea,* guarana† and cola nut,‡ and so far as we know, these are the only plants of the whole vegetable kingdom that contain *Theine*. But we now hope that we have discovered a rival to the *Theine* group in Coca, as it possesses powers that will render it still more useful as a beverage. For those who have much mental work to get through, Coca will prove a stimulating, soothing and refreshing beverage; and to those having to undergo much physical exertion, it will be found of great value from its sustaining, recuperative and refreshing qualities. I belive we have found in it the popular beverage of the future, that which our tectotal friends have been so long searching for, viz., an article that will, in physiological utility and popular estimation, take the place of alcoholic drinks. Tea and other substances, of which the active principle is *Theine*, increase the waste of the body especially when the amount of food is insufficient, whereas Cocaine has a conservative and sustaining influence under similar circumstances. Again, tea is sometimes taken to prevent sleep, and Coca, in full doses, has the same effect, while in moderate doses it induces sleep, and will be found specially useful in insomnia as the result of overwork. We have thus, you see, a very useful agent in this substance, and what is now chiefly wanted is the discovery of some method of preparing it that will make its use as easy as that of tea or coffee, and the resulting preparation as grateful and acceptable to the million. Mr. Holmes, Curator of the Pharmaceutical Society's Museum, writes to me:—"It is a useful digestive and tonic, and if the leaf could be dried in the *form of tea*, so as to be used like coffee as an after-dinner beverage, and flavoured like the finest Chinese tea either by a carefully-watched fermentation before drying or by flavouring with Jasminum sambac, Rose flowers, Olea fragrans, Aglaia odorata, or any other delicate perfume that would mask the flavour of Coca, it might be introduced over here."

It now therefore remains for the planter and chemist to devise some mode of preparation, that will render the substance acceptable as a dietetic beverage in Europe. A fluid extract which is now in use to a small extent, apparently retains all the active properties of Coca; but it is treated more as a drug than as a seductive and comforting luxury, and what we want is an article that will appeal to the palate of the many, just as tea and coffee do. As further uses are found for Cocaine, its consumption will increase, and if we also had a tea-like Coca, the demand for the leaves would be very large. The subject I feel sure, only needs to be brought to the notice of our enterprising planters to secure their attention, and if the culture of Coca can be made profitable, the South Indian planter will very soon take it up.—*Madras Times.*

Sugar as Feed for Stock.—The low price of sugar in England is inducing farmers there to inquire into the advisability of feeding it to fattening stock. In this country we always feed more or less sugar to cattle in the stalks of Indian corn and sugar cane, and in the sugar beet. Sugar is very fattening, and, if our sorghum industry proves successful, the course grades of sugar may be produced cheaply enough to be fed to stock which it is especially desirable to fatten rapidly.—*Prince Edward Island Agriculturist.*

Indian and Ceylon Tea.—The Annual Report of Messrs. Geo. White & Co. on this market will be read (see page 838) with interest by Ceylon planters. It will be seen that the increased area planted in Ceylon and Sylhet, is not regarded as a discouraging sign from the sellers' point of view, as, it is judged, future requirements will cover the increased production. Messrs. White & Co. give the warning so often repeated in our columns already, that quality must not be sacrificed to quantity, if "pecuniary result" is the object of the planter, and to obtain a good name for his plantation. The hints given as to preparation deserve careful consideration.

Mossy Tennis Courts.—In reply to the inquiry of H. N. in your last issue, as to the best method of removing moss from tennis courts, I cannot recommend a more certain cure than an application of Norwegian fish guano. It destroys moss, and brings up in its place the finest grasses of a rich olive-green. The lawns dressed with this manure are simply perfection in the closeness of growth, and are consequently well able to resist the wear and tear of constant play. With regard to the query by "Corsair," I do not consider that any external remedy will entirely destroy weeds; they must be eradicated with the fork. But the growth of fine grass, stimulated by fish guano, tends very materially to prevent their extension. After all possible weeds are extracted, and the ground dressed with fish guano, I recommend a light coating of coke dust, which washes into the soil, makes a remarkably firm surface, and is prejudicial to the formation of worm casts. I have played an an absolutely perfect lawn produced in this manner, and on my recommendation, our club courts are now being similarly treated.—C. C. B. (Blackheath).—*Field.*

Whitewash for Outbuildings.—The following recipe is timely and reliable:—"As we have often recommended good white-wash, well applied to fences, sheds, rough siding, and the walls and ceiling of buildings, cellars, etc., has a highly sanitary influence, as being very preservative in its effects. To be durable whitewash should be prepared in the following manner:—Take the very best stone lime, and slake it in a close tub, covered with a cloth to preserve the steam. Salt—as much as can be dissolved in the water used for slaking and reducing the lime—should be applied, and the whole mass carefully strained and thickened with a small quantity of sand, the purer and finer the better. A few pounds of wheat flour mixed as paste may be added, and will give greater durability to the mass, especially when applied to the exterior surface of buildings. With pure lime, properly slaked and mixed with twice its weight of fine sand, and sifted wood ashes, in equal proportions, almost any color may be made by the addition of pigments. Granite, slate, freestone and other shades may be imitated, and without any detriment to the durability of the wash. This covering is very often applied, and with good effects, to underpinning, stone fences, roofs and the walls of barns and other outbuildings. Probably the pure whitewash is more healthy than the colored, as its alkalescent proprietors are superior, and when used in cellars, kitchens and sleeping apartments produces salutary results. No person who regards the health of his family should fail to have applied a coat of such white-wash every spring. Country places, especially farm outhouses, fences, etc., are greatly improved in appearance by an annual coat, and it will add to their permanency much more than many would imagine. As we all know, is is cheap and easily applied, so that neither expense nor labour can be pleaded against it."—*Baltimorean.*

COFFEE AND TEA PLANTING ON CEYLON HILLS.

GROWTH OF TEA AT HIGH ALTITUDES—MAGNIFICENT APPEARANCE OF COFFEE—A SIGHT OF BEAUTY—COFFEE DOOMED—UNFULFILLED PROMISES.

LINDULA, 10th April.

In order to see how well-suited high altitudes in this region are for tea, one has but to look at the wonderful growth of eighteen months old on the new clearing on Inverness. But, before treating of the prospects of tea in high altitudes and at low levels, I really cannot refrain from noticing the truly beautiful, I might say magnificent, appearance of coffee up here. I walked over a considerable portion of the estate whence I write this morning, and my companion and I could not refrain from exclamations of delight as we beheld expanses resembling emerald strewed over and adorned with rolls of aggregated snow crystals, the idea of snow being at once, however, dissipated by the sweet jasmine-like odour which loaded the hot, moist atmosphere. Than a well kept, carefully and evenly pruned coffee estate such as this is, when in full blossom, there are few sights more beautiful. But I am bound to confess that the spectacle on which I first looked was surpassed when we arrived at the confines of an adjoining property, higher up the Dimbuldanda valley, where coffee had yielded such disappointing results, that, preparatory to its supersession by tea, a single long sucker had been allowed to grow up on each bush. Those suckers, several feet in height, pyramidal in form and with regular tiers of branches growing out from the main stem, were covered with a perfect blaze of blossom, and the effect of an expanse of such bushes was as much more striking than what I have already described, as a grove of natural growing trees is superior in beauty to the most evenly pruned hedge. But it is not for beauty of blossom or sweet odour that we cultivate coffee, and, I fear, the period is not far distant when the well pruned coffee I referred to will be subjected probably to the same forcing process so as to secure one or two good crops of berry before the fiat of execution goes forth against the trees which have ceased to respond to cultivation with compensating fruit, however rich they may be in blossom, and, in periods like the present, when leaf-fungus and scale insect are absent, luxuriant in foliage. Looking at collections of withered leaves beneath the bushes, we know how the energies of trees have been exhausted in clothing themselves with repeated coats of foliage, and therefore we have ceased to hope for fruition in any proportion to the promise of blossom. Last year, we felt we had a good right to expect, if not 2,000 bushels of parchment coffee, at least 1,600. But the result was only 1,400, and, although this was far better than the outturn in other cases, it was no more remunerative than several previous crops had been, and when, even with the richest promise in the shape of green foliaged bushes and snowy blossom redolent of sweet odours, returns of crop in successive years become "small by degrees and beautifully less," it is of little use to exhort us not to lose our faith in a product which, when we do obtain it, goes to a bad market. Estate owners will not spend money on the upkeep of coffee either, merely to prevent a repetition of the mistake of having wide unbroken expanses of one cultivated product. Necessity as well as reluctance to abandon what has cost so much will prevent the reckless destruction of coffee, but, you may rely on it, that in a large proportion of cases, even the best coffee is only retained as yielding the means for its own supersession by tea. But more on this point hereafter.

The patanas are gradually passing from yellow to green, while the luxuriance of all bush and tree vegetation is rich beyond expression. The tea flush can literally "be seen growing," while the coffee blossom is perfect in beauty and perfume. Would that in the latter case we could count our fruit in proportion! But there is certainly room for hope.

REPORT ON INDIAN TEA:

GEO. WHITE & CO.'S ANNUAL INDIAN TEA REPORT.

London, 2, Great Tower Street, E. C., 20th March 1885.

CLOSE OF LAST SEASON.—At the time of issuing our last Annual in March 1884, we find that there was a dull dragging market with an over supply of common and undesirable kinds, and prices about on a par with those ruling at the same period of 1883. After Easter there was a better enquiry for good tea, but poor quality continued very depressed, especially common pekoes, a large quantity of which were of old imports. During April and May the enquiry for good to finest improved gradually, and prices hardened 1d to 3d per lb., but common to fair medium were neglected, though apparently very cheap.

After Whitsuntide the demand was limited except for good teas, and notwithstanding that May deliveries were the largest on record, viz. 6,062,000 lb. there was a very quiet tone all through June. The first New Darjeelings were offered on 5th of that month, and being above the average in quality sold well. Later arrivals did not meet with so much attention.

GENERAL REMARKS ON PRESENT SEASON.—The Season, which to all appearances will close earlier than usual, has been on the whole rather devoid of interest and free from speculation, and probably not a remunerative one, except to a very few fortunate garden owners and shippers. The depression in prices, most noticeable towards the close of the year, was in a great measure due to the very large quantity placed on the market during October and November; and it would be to the interests of Importers, if they could regulate the shipments or the sales to some extent in accordance with our requirements.

Had the figures regarding the outturn and the quantity available for shipment to Great Britain not been so misleading, perhaps more of the Tea hurried forward for sale at the close of 1884 would have been held over for a time and thus met a better demand. If, therefore, some means of gathering earlier and *reliable* information as to the probable export could be adopted, it would no doubt assist in keeping prices steadier by giving importers some confidence in occasionally holding back supplies from an overstocked market. During the past few years also buyers have not purchased freely until after the August bank holiday, so that until then it scarcely seems advisable to press sales, as the demand does not become general.

Fine to finest with real quality have been scarce throughout the season and have kept up well in price, but the supply of common and medium has at times been in excess of the demand. The quality of the crop has varied considerably, for short periods it was very good (*i. e.*, arrivals in August, January and February) but on the whole poor, and in many respects similar to that of 1882-3. The market at the present time appears also to be very like that of March, 1883, after which month there was a large business at an advance on prices previously ruling.

The statistical position of both Indian and China Tea is apparently good, and so far as can be gathered the crop of 1884-1885 will at the present rate of deliveries be all absorbed. In fact the consumption, owing partly to the low range of prices ruling for some time, has outstripped the increased production, and though larger acreages are coming into bearing, especially in Sylhet and Ceylon, it would appear that in all probability the increase may be wanted to meet the requirements of the future. Further complications between France and China also may check, if they do not altogether for a time stop, shipments from the latter country; the extra duty of 1½d per lb., making in all 3d to 4d per lb., which the Chinese Government proposes to place on the export of tea should moreover indirectly benefit those interested in India, Ceylon and Java.

Prospects for the coming season seem favourable, though a higher average than last year's should not, we think, be depended on with an increased yield. The stimulus given to the market by the duty scare may cause a reaction after the Budget is announced, whether an alteration takes place or not. If an addition is made it will tend to increase the demand for teas for price, and if no change is made things will probably settle down as before. Fine to finest will in all probability be much wanted until September or October, and high prices may be obtained for them until buyers have replenished their stocks. During the past season a few fine, pungent, lightly-fermented teas have sold well, partly owing to their scarcity. The demand for these is rather limited, and it would be dangerous to make too much, especially if the quality was not good, but a little might be tried from fine leaf. It has now been pretty clearly shown that, with a few exceptions, a large quantity does not pay as well as a smaller amount of better quality. The temptation to swell their outturn per acre should not be yielded to by Managers, for although the figures may look well on paper as regards the total of Tea manufactured, the pecuniary result often proves anything but satisfactory. A considerable portion of the past season's crop has again consisted of Teas with fair quality, and tolerably bright infused leaves, but the infusions were light in the cup. This is partly accounted for by unfavourable weather, but is also a sign of bushes weakened by insufficient cultivation, over plucking, and the allowing a large quantity of seed to ripen on the bushes (which the demand from Ceylon and elsewhere has encouraged of late years), the the result being that they are more easily attacked by red spider and other blights, and consequently the Tea made from leaves thus affected is sure to lack strength and quality.

Manufacture.—The different stages of manufacture have of late engaged the attention of Planters in India and Ceylon, and a great deal of correspondence has been carried on with regard to it, both privately and in the different journals connected with Tea.

Some advocate fully withered leaf, as it produces Teas with fine rich flavor, which the same leaf less withered does not possess.

Rolling by machinery is almost general, though owing to the leaf being sometimes submitted to too much pressure the juice is partly lost.

Fermentation, one of the most important processes, does not appear to be thoroughly understood by the majority of planters, and is a subject which would well pay scientific investigation.

The cause of the poorness of a larger portion of this Season's crop has been shifted from "climatic influence," on to the shoulders of the Drying Machines. As, however, it is a well-known fact that good and bad Teas have been produced by the same machines, and even from the same gardens, it would appear that sufficient experience in the use of them has hardly yet been attained.

Firing at a very high temperature and briskly is advocated by a few, but it is generally considered that tea fired at a moderate heat is usually the best.

The chemistry of tea has been talked about for many years, and is no doubt a most necessary portion of manufacture. In 1881 we wrote rather fully on this subject, from which we will quote the following:—

"There is little doubt that large quantities of leaf properly grown and even properly withered, are spoilt annually for want of knowledge in the details of curing, which we believe is still in its infancy. The leaf after plucking has to pass through certain stages of fermentation and chemical action, which ought to be carried on with the utmost care and supervision. It has, in fact, to be *cooked*, and like other food is often spoilt in the cooking. Under the old fashion, that is to say the system of hand rolling, &c., there used to be some very fine tea made, and we are inclined to think that one of the processes, viz., that of panning, which has been discontinued, might be revived to advantage;" which is quite as true now as then. We also drew attention at the same time to a Calcutta circular suggesting that planters should exchange ideas regarding manufacture and economy in working more than was customary. This has been done of late, especially amongst Ceylon planters, who ventilate their ideas and experiences openly in the newspapers, and with Tea Associations in London and Calcutta, there should be ample opportunity of disseminating knowledge. We would suggest that a fund for experiments should be started, under the control of one of these Associations, who should appoint an able man or men to be employed solely in making experiments for the common weal, more especially as to the chemical processes of withering, fermenting, firing, etc.

Ceylon and Java are expected to produce about four-and-a-half millions each during the coming season, which will tend to increase the quantity available. Planters in the former island appear determined not to be left behind in the race, which they have been carrying on so well for the past two years, while the produce of the latter has shown a great improvement, some of the teas having full rich flavor like hill-grown Indians or Ceylons.

To obtain a good name for a garden should be one of the chief aims, as many buyers will give pence per pound more for a mark which they have become used to, and of which they can depend upon obtaining a regular supply. Whilst on the subject of marks we would mention that it is questionable whether the elaborate ones on some packages do not deter the produce of a garden from being well-known. The plain name of the Estate or Company is much more likely to be remembered and asked for than several letters in the corners of a double triangle. Besides the name of the Estate, the garden number of the package and the description of tea are the only things requisite, the gross and tare is unnecessary and often misleading. With Calcutta purchases a distinct shipping mark as in China Teas is also necessary, otherwise different importers' invoices are apt to be mixed in the warehouses.

Packages and size of breaks.—As regards sorting, the tendency to make as few sorts as possible is gaining ground steadily, and we strongly advocate it especially on small gardens. We still look forward to the days of unassorted Tea, but the time for that has not yet arrived.

The proportion of breaks under 20 chests in garden invoices, and of subdivided lots in Calcutta purchases, has been less this season. Now that it has been arranged that all parcels under 8 chests are sold by themselves after the sales, it is the more necessary that the breaks should be large so as to ensure the attention of all the buyers. For fine and finest 20 to 50 chests (or half chests) and 50 to 100 chests for common and medium descriptions are the best.

The proportion of half-chests this season has been below the average, and there has consequently been a demand for them; if not in excess, Teas packed in this way often sell better than in chests.

Boxes, especially of flavoury (self-drinking) Teas, such as Darjeelings and Ceylons have also been in request, and are still sought after as they are often sold direct to the consumers in their original state, that is to say, without admixture. They should, however, be under 28 lb. gross, as they are then not subject to any draft, whereas if over that weight they are treated as chests.

During the season a large quantity has been sold as "Factory bulked" on the whole with satisfactory results, and it is only a work of time for London bulking to be a thing of the past.

The system of weighing net appears to work satisfactorily when care is taken to avoid irregularity, and that the weight declared to the Customs is the same in every package in a break. Complaints have, however, been made in many places that this has not been attended to, the result being that all the packages, although bulked in India, have had eventually to be turned out to ascertain the separate net weights, and some buyers positively refuse to purchase parcels thus treated. The greater portion of the Tea shipped to England from all parts, now arrives in such a condition with regard to weight and tare, that there is no need for turning out in the London warehouses, except in the case of those gardens where no bulking facilities exist.

Although the suggestions previously thrown out about central bulking establishments in the tea-producing districts may not be feasible, why should not experienced buyers make periodical trips to the different districts and buy up the unassorted Tea, and send it to Calcutta to be sorted and packed there? All parcels not quite even in quality might very easily be bulked in Calcutta prior to sale in that market, and refired before shipment,

so as to avoid the serious discrepancies which often occur between the sale samples there and the Tea itself after being turned out and mixed in the London warehouses. It stands to reason that it must be difficult to produce a fair sample to sell a parcel by in Calcutta, if it is so irregular in quality as to necessitate its being bulked on arrival in England.

PURCHASES IN CALCUTTA.—Rather more than half the crop has been shipped on garden account this season; the quantity sold in Calcutta to 24th February having been 322,000 packages against 344,000 packages to same date last year. Early purchases gave good results to shippers; later imports, on the other hand, did very badly, but arrivals since December and January have again proved profitable, especially in the case of fine Pekoes and finest descriptions generally. Buying in Calcutta, as in most other places now-a-days, is overdone, and the competition is so keen that great caution is required, owing to the very sensitive market there, which is influenced by telegrams sent from this side. Buyers who have confined themselves to fine and finest steadily this season, will probably have very little to complain of: but purchasers of common kinds, until recently, have had a bad time of it.

ASSAM.—Estimated Crop 1884-85. lb. 32,500,000. Season 1884-85.—Similar to previous season, many well made, but light in cup. During August and September, some very desirable teas were received, quite up, if not superior to those of the past few years. 1883-84.—On the whole rather below the average, well-made leaf but large proportion, light in cup. Few strong ones with quality realized high averages. 1882-83.—Quality very poor at first, then better but again fell off; towards the close a few very good, especially brown leafed (autumn tint ones.)

CACHAR AND SYLHET.—Estimated Crop 1884-85. lb. 17,500,000. Season 1884-85.—Early part of season undesirable as a rule, with the exception of several favourite marks which have kept up quality throughout. Later arrivals were much better. 1883-84.—First arrivals undesirable, but later on considerable improvements, towards the close some very useful. 1882-83.—Poor at first, then great improvement, especially on Sylhets, some very fine.

DARJEELING, KURSIONG AND TERAI.—Estimated Crop 1884-85 lb. 10,500,000. Season 1884-85.—Quality very irregular, but on the whole disappointing. Early arrivals good, especially some sold in August, but September imports shewed a great falling off in the cup. Towards the close some choice parcels were received. 1883-84.—Fairly good all through the season, some really choice flavoured lots commanded high rates. 1882-83.—Crop generally much inferior to last season, choice flavoured teas in great request and a few really fine parcels realized very full prices as compared with inferior sorts.

DOOARS.—Estimated Crop 1884-85 lb. 10,500,000. Season 1884-85.—On the whole good, and a great improvement on previous year. Some very desirable full flavoured parcels, especially the autumn pickings. 1883-84.—Disappointing as a whole and gradually fell out of favour as compared with last season, through lack of keeping quality. A few full autumn flavoured towards the close sold well. 1882-83.—Fairly good at first. Crop generally above the average, some very choice parcels towards the close.

KANGRA VALLEY, KUMAON, AND DEHRA DOON.—Estimated Crop 1884-85 lb. 3,250,000. Season 1884-85.—From the former some very choice invoices received at early part of season. The quality fell off later, owing to the unfavourable weather. Recent shipments have again been good. From the last two districts quantity received was very limited. 1883-84.—Several of former very fine but crop on the whole below the average. Kumaon Teas rather better, but Dehra Doon in very short supply. 1882-83.—Disappointing throughout, very few fine, though much wanted; last two in very short supply, and quality poor. Chiefly used for local consumption and Asian trade.

CHITTAGONG.—Estimated Crop 1884-85 lb. 1,250,000. Season 1884-85.—On the whole fair, but quality irregular, similarly to that from other districts. 1883-84.—A few choice parcels especially at beginning of the season, but later shipments rather disappointing. 1882-83.—Fair at first, then some exceptionally strong teas with fine flavour of desirable kind, which commanded very high prices, similar to teas produced some years ago.

NEILGHERRIES.—Estimated Crop 1884-85. lb. 1,250,000, Season 1884-85.—In short supply, and quality with a few exceptions below the average. These teas, like Kangras, command very full prices when really fine. 1883-84.—Quantity limited, but quality rather improved, 1882-83. Short supplies, quality of those received generally undesirable.

CEYLON.—Estimated Crop 1884-85. lb. 3,000,000. Season 1884-85.—Still in favor owing to their useful qualities. Some undesirable shipments however have realized low averages. Demand likely to continue for all parcels with full flavor. 1883-84.—In considerable request at steadily improving rates thoughout the season, the demand for these growths having become general from all parts of the United Kingdom. 1882-83.—Outturns and shipments to Great Britain much larger, quality generally good, and fast gaining favour with retail buyers for "self tea," and mixing purposes.

Total Estimated Crop 1884-5 lb. 68,000,000. From which deduct say one-and-a-half millions for local consumption, and two-and-a-half millions for shipment to the Colonies, America and the Continent, which will leave about sixty-four millions available for Great Britain.

GEO. WHITE & Co., Tea Brokers.

CULTIVATION has been so greatly neglected in Upper Burmah, on account of the disturbed state of the country, that over 7,400 tons of rice, husked and unhusked, were imported across the frontier from British Burmah in the month of February.—*Madras Mail.*

STATISTICS of some interest to India have just been supplied by the Secretary of the State of Michigan, one of the great wheat-growing centres of the United States. From these figures it will be seen that farmers are not suffering quite so much over there as we would imagine from the low price of wheat, and it would be interesting to know how the Indian wheat-grower fares by comparison. Here are the figures:—

	Southern 4 Tiers of Counties.	Counties N. of Southern 4 Tiers.	State.
	Dols.	Dols.	Dols.
Cost of ploughing	1·60	2·06	1·79
Cost of fitting for seed... ...	1·20	95	1·14
Cost of fertilisers	1·03	1·30	1·08
Cost of seed	1·64	1·68	1·65
Cost of drilling	37	37	37
Cost of harvesting	1·63	1·47	1·59
Cost of stacking...	73	61	71
Cost of thrashing	1·59	1·93	1·51
Cost of marking...	79	1·04	87
Interest at 7 per cent	4·12	2·22	3·57
Cost of repairs	91	1·13	95
Total cost of producing and marketing one acre of wheat	15·70	14·21	15·16

The *Economist*, remarking on these, says:—

Subtract from the above totals the value of straw per acre, and there remains as cost of producing and marketing the wheat grown upon one acre in the southern four tiers of counties 14·25 dollars; in the northern counties, 12·20 dollars; and 13·67 dollars as the average for the State. Dividing these amounts respectively by the average yield per acre, the cost of producing and marketing one bushel of wheat in the southern four tiers of counties is found to be 7 17-10 cents; in the northern counties, 70 3-10 cents; and the average cost in the State, 71 cents. The average price of wheat on Jan. 1, 1885, was, in the southern four tiers of counties 71 5-10 cents per bushel, and in the northern counties 70 9-10 cents per bushel. The crop of 1884 sold at these prices would bring the farmers of the State very nearly the amount of their expenditure for fertilisers, seed, and repairs, 7 per cent interest on the value of the land on which the crop was raised, and day wages for their labour.—*Overland Mail.*

TEA MANURES.

Pending the day when the tea-planters of Ceylon will be able to invite Mr. John Hughes, F. C. S., to repeat his visit to this island, we cannot do better than pay attention to the sound and thoroughly practical advice which he has been good enough to send us in the following paper. It will be observed that Mr. Hughes bases his advice on the information published as to crops already gathered of tea on some of our richer plantations. He then shows us, as only a scientific agricultural chemist can, what such crops mean in reference to our soils, and the withdrawal of the various indispensable crop constituents. Finally, he gives us in the plainest form his counsel as to how the principal constituents needed for tea plantations in Ceylon can be supplied; and it only remains, therefore, that merchants who are in a position to sell to the planters finely-ground steamed bones, castor or cotton cake, should make the fact known. We trust that several experiments will at once be made in accordance with Mr. Hughes's suggestion in different districts and at different elevations, so as to have the results made known for guidance in the future. Such results would be most interesting to Mr. Hughes himself, and, as we have already said, he might by-and-bye be got to pay another visit to our planting districts! His paper is as follows:—

It has been very properly pointed out by recent writers in the *Ceylon Observer* that the actual yield of tea per acre must not be taken as a true guide to the special merits of one estate against another, for the *quality* as well as the *quantity* must be considered.

In these days of new production it would be a serious mistake to expect that quantity should be able to make up for an inferiority in the quality, more especially as the tea industry being comparatively new in Ceylon, and its character hitherto rendered famous in the Mincing Lane markets by reason of its fine flavour and dark-colored liquor, it is most important that the consignments should only be of the best obtainable quality. These practical points will, of course, naturally occur to the minds of experienced planters, but with plenty of available labour, well-appointed machinery capable of turning out a large yield per diem, there is always a strong temptation to pick coarsely rather than finely and so increase the bulk. It should however be remembered that a yield of 1,000 lb. to 1,200 lb. of prepared tea per acre must be regarded as a somewhat exhausting crop, and that, while newly-opened estates may, and probably do, produce so large a quantity for the present, yet we must expect a falling-off in a few years' time as a result of continued and heavy cropping. Indeed, unless the soil is specially rich or some help in the form of manure be afforded, the peculiar forcing nature of a favourable climate only contributes to the more rapid exhaustion of the soil.

According to Peligot, a distinguished chemist who has devoted particular attention to the analyses of tea, the leaves of this plant are especially rich in nitrogen; thus in perfectly dried tea at 110° C. he found:—

In 100 parts of Pekoe	...	6·58 of nitrogen.
,, Gunpowder		6·62 ,,
,, Souchong	...	6·15 ,,
,, Assam	...	5·10 ,,

From analyses of Ceylon tea made by myself I believe the average proportion of nitrogen is somewhat less than is usually found in ordinary Assam tea, and I think we may fairly assume that in 1,000 lb. of Ceylon tea as sold we have:—

Nitrogen	...	45 lb.
Potash	...	22 ,,
Phosphoric acid		8 ,,
Lime	..	2½ ,,

Now, 45 lb. of nitrogen is as much as would be removed per acre by an average crop of wheat, barley or oats, allowing for the nitrogen contained in the straw as well as in the grain; and we know that continuous corn-growing is very exhausting and can only be done under the most favorable circumstances. Further, it is always usual to return the straw in some form to the land so that at least a quarter of the original nitrogen removed is really returned. Again, in the matter of potash, an average crop (30 bushels) of wheat removes 10 lb. in the grain, and ... ... 18 ,, in the straw, also (40 bushels) barley removes 10 ,, in the grain, ... 24 ,, in the straw, and (45 bushels) oats removes 9 ,, in the grain, ... 30 ,, in the straw. Therefore, in respect of potash, we must regard a yield of 1,000 lb. of made tea twice as exhausting as an average crop of the abovenamed cereals, assuming that the straw of the latter is always returned to the land.

But Ceylon soils are somewhat poor in potash readily available for plant-food, and I should therefore think it most desirable that potash as well as nitrogen should eventually be applied to tea plantations *in* the form of some manure.

Next we come to the phosphoric acid which stands at 8 lb., which seems small, but practical experience plainly shows the good results of the application of phosphatic manures, and the analysis of a great number of Ceylon soils clearly indicates the necessity of supplying this most important constituent of plant-food.

Lime stands last and amounts to only 2½ lb. from 1,000 lb. of tea, but we find that an average yield of corn, whether wheat, barley or oats, does not contain: in the grain more than 1 or 2 lb. per acre, as against 8 or 9 lb. in the straw.

There is, therefore, no direct necessity to supply lime, though it may be indirectly useful in the preparation of plant-food, and for the retention of carbonic acid brought down with the rain, and thus assist in the future disintegration of the granite rock.

Having thus briefly noticed the few leading constituents which require to be applied in the form of tea manure it is only necessary to remark that nitrogen can be most usefully provided either from castor, rape, decorticated cotton cake, dried fish, shoddy or cattle manure. That potash can be obtained either as muriate or as sulphate of potash; the latter probably being the most suitable to Ceylon soils.

Phosphoric acid can be applied either in small doses of concentrated super, containing 20 per cent or more of soluble phosphoric acid, or else in the form of finely-ground steamed bones which moreover are also rich in nitrogen. As the latter can be obtained at Colombo at a reasonable rate, planters can make a practical trial for themselves. Lime will be contained also in the super, and the bones will not in such a case have to be applied separately.

In conclusion a mixed manure made from the materials can be so compounded that a 100 parts would contain

Nitrogen	...	4 per cent
Potash	...	3 ,,
Phosphoric acid	...	10 ,,

and this could be applied this next season by way of making a practical experiment.

Highly concentrated manures like sulphate of ammonia, nitrate of soda, and similar readily soluble

compounds would be both too stimulating, and tend to produce a coarse growth of leaf.

John Hughes, F.C.S.

Analytical Laboratory, 79, Mark Lane, March 20th, 1885.

EARTHWORMS.

To the Editor of "Nature."

I see, in your issue of October 9 (vol. xxx. p. 570), an interesting communication entitled "A Gigantic Earthworm," in which the writer refers to worms of large size being fairly common in parts of Cape Colony. I may mention that here in Ceylon it is not an unfrequent sight to see two or three of these big worms in the same day, after showers, though I would not pronounce them to be exactly common. I have seen some fully four feet in length, and about the thickness of one's little finger. They are of a pale slaty-bluish colour, and appear, on close examination, to have faint prismatic colours over parts of the body. These worms are seemingly not confined to particular soils or altitudes, as I have met with them at elevations of from 2,000 to 4,000 feet above the sea. Owing to their seeming inertness of body, the *lob-worms*—as I have frequently heard them called—soon fall an easy prey to swarms of small red and black ants, that attack the victim as it lies on the ground.

Passing from large to small, I may mention a curious earthworm that I found to be very common in North Borneo. The chief peculiarity about this worm is the size of its "cast," this being about four inches high by one inch-and-a-half across the top, which is made cup-shaped or with a marked depression, for the purpose, I believe, of catching water. The stem—if I may apply the word—of the "cast" is about an inch in diameter, strongly built of rows of earthy matter laid circumferentially, widening towards the top into a lip that forms the side of the cup. Sometimes a leaf may have fallen on the "cast" in the course of erection, and this is at once built over, so that part of the "cast" may be seen above and part below. The worm itself is very small, and hard to secure. I have found the only method of catching them was to suddenly break off a fresh "cast," when one could get a glance of the worm as it rapidly withdrew into the ground. It is of a fleshy red colour, and about the thickness of the stem of a crow-quill pen, but I do not know how long, as I never succeeded in extracting a whole worm from its burrow. The "casts" are very numerous, and weigh, I should think, quite an ounce each, and are to be met with both in the forest—as well as in gardens—and cultivated land. I also found them close to the banks of rivers that were sufficiently near the sea to be considerably impregnated with salt, so that I conclude from this that salt water is not destructive at least to this species. Frederick Lewis.

Bogawantalawa, Ceylon.

NEW PRODUCTS AND PLANTING PROSPECTS FROM COLOMBO TO MATALE.

The drought seems to have touched up the Liberian coffee and cacao between Polgahawela and Rambukkana, but the fresh foliage of the latter is already perceptible. Shade is being provided here, I note, and on one estate the regular plantation of well-grown jak trees was particularly noticeable.

Matale, after the long drought, was looking greatly refreshed by copious afternoon showers. Cacao in the flats along the line had not made the progress I expected it would have done on such situation and soil. It does better on gentle slopes in good soil when thoroughly protected from wind and under light shade. From what I have seen on this trip, I should say that moderate shade is, if not a necessity, yet eminently desirable. The effects of the long drought are far more perceptible where no shade exists than where it has been provided, as evidenced by blackened tops of branches not yet hidden from sight by the luxuriant growth of new foliage now coming forward. In exposed situations mealy bug seems to have a partiality for cacao pods, but I could not learn that much actual harm had been done by it.

Coffee has come round wonderfully since the attack of black bug last year, but I fear the coming crop will be lamentably short, if indeed there is any at all, seeing that the pest has evidently only retired to await a more convenient season for a fresh attack. Passing through a field famous for past glories, and even now showing wonderful recuperative powers, the superintendent said to me: "All this looked absolutely dead only a few months ago: it will, of course give nothing this year, but surely it will do well next year and is worth a light pruning." "Stop a moment," said I, and a little search revealed the young succulent shoots covered thickly with their deadly enemy: being still in the early stage, their green colour, had at first shielded them from observation. "Take what crop you can get, and be thankful, and don't lay out a cent that you can avoid," was my disinterested advice; but then I must own that I have long been a dreadful pessimist as regards coffee.

Cinchona in this district is far behind the younger districts in point of growth, but, though stunted, it struck me as comparing favourably in point of its healthy appearance

Cardamoms seem momentarily to occupy the first place in the estimation of the inhabitants; and no wonder when you hear of one fortunate possessor shipping 33,000 lb. dry cardamoms from 50 acres, or about one-fourth of the estimate of the year's shipments.

Tea clearings are also much in vogue. Apparently my friend had several in hand aggregating 120 acres under the shadow of Ettapolla, on land which in its day has produced some of the finest coffee ever shipped from Ceylon: and, as far as I can see, judging from tea planted there some five or six years ago, he is in for a good thing, if the rainfall proves satisfactory. I understand the mean for a number of years is 100 inches, but last year there was a deficiency of over 40 inches. The drought seems to have affected native cultivation quite as much as our hill products. Village paddy is improcurable and village rice R3·75 per bushel, whereas the imported article can be had down in Matale for about R3·45. Dwellers in Anuradhapura support the demand for railway extension—northwards. H.

MARKET-GARDENING AT NANUOYA.

A correspondent entitled to speak with some authority writes as follows:—

"It is a thousand pities that some competent hard-working individual does not go in for a market garden, on a large scale, in the neighbourhood of Nanuoya. If conducted properly it would pay handsomely. Even putting aside the inhabitants of Colombo and Kandy—who no doubt would be glad to take large quantities—I think a large and paying business could be carried on in supplying the ships which call at Colombo with fruits, flowers and vegetables."

The hint ought to be taken by an enterprizing planter of the right sort who may be out of employment. We have no doubt, that the requisite piece of land if available on the property surrounding the station could be obtained for such a purpose on easy terms. We should think steamer agents would give due encouragement to such an undertaking if carried out systematically.

The same correspondent sends us a number of practical extracts bearing on Horticulture which will find a place in the *T. A.* One cutting on the comparative value of garden manures and wood ashes will be of special interest to local cultivators, while, in respect of another on the trenching of garden soil, our correspondent says:—

"This is the grand secret of vegetable growing, and, if our upcountry gardeners (?) would only cultivate in this way, there is no reason whatever why the people in Colombo should be short of such vegetables as peas, cauliflower, potatoes, &c., &c.—a truck-load of vegetables should leave Nanuoya every day."

Another extract giving a "simple treatment to protect roses against their enemies"(insects, mildew, &c.) will be elcomed by many cultivators of roses in the hill districts. Further information refers to tuberous begonias (which so many people complain do not thrive well in the second year in Ceylon); and to torenias, very beautiful plants suitable for verandahs, but, like those of many other plants, the seeds are generally covered too deep and so never come up. For the detailed information in each case, we can only refer to the *T. A.*

TEA GARDEN REPORTS.

The Managing Agents of the Sungoo River Tea Co., Ld., have issued their Report for the year ended 31st December 1884. The outturn for the season was 1,190 maunds, being 110 maunds less than the estimate. This short yield was due to bad weather and red spider blight; therefore the manufacture was not of good quality. The average realized for the crop, exclusive of 2,980 lb. shipped to the Colonies, was 8 annas 3 pie. The estimates for the current season are for 1,225 maunds, at a cost of R52,300.

The Managing Agents of the Burkhola Tea Co., Ld., have issued their Report for the year ended 31st December 1884. The outturn for the season was 1,336 maunds, being 36 maunds in excess of the estimate. The gross average realized for the Black Tea was 9 annas 3 pie and for the Dust 3 annas 6 pie as compared with 10 annas 9 pie and 2 annas 8 pie respectively in 1883, The Profit and Loss Account shows a profit of Rupees 8,877-3-4, out of which it is proposed to pay a dividend of 3 per cent. on the subscribed capital. The estimates for the current season are for 1,300 maunds, at a cost of R43,583.

The Directors of the Monacherra Tea Co., Ld., have issued their Report for 1884. The accounts show, after the Managing Agents' allowance is written back, a loss on the season's working of R4,201-9-6, leaving at debit of Profit and Loss Account R3,171-15-5, after bringing forward the balance at credit from season 1883. The total outturn for the season was 1,942 maunds as compared with 1,986 maunds for 1883 and 2,169 maunds for 1882, and the average prices realized were lower than 1883, but higher than 1882 averages. Estimates for 1885 are R87,918 for 2,025 maunds of Tea.

The Managing Agents of the Bengal Tea Co., Ld., have issued their Report with audited accounts for the year ended 1884. The total outturn for the season was

Mds.	2,282-8	of Fine teas	as compared
„	374-24	„ Coarse „	with
Mds.	2,133-33	Fine teas	for 1883,
„	460-33	Coarse „	

and the average prices realized were As. 8-11 and As. 5-1 respectively as compared with As. 10-2 and As. 5-2 respectively for 1883. The accounts show a loss of R6,140-8-8 for the season which deducted from the amount brought forward from last year, leaves R2425-14-8 at credit of Profit and Loss Account.

The Directors of the Bisnauth Tea Company Limited have issued their 43rd half-yearly report for the year ended 31st December 1884. Total outturn of 6,041 maunds 10½ seers packed tea, of 208 maunds 29½ seers below the estimate, and 174 maunds 5 seers above the outturn of the previous year. According to the latest telegraphic advice received on the 12th March, the net average realized for the quantity sold to that date, viz. 368,745 lb. was 1s 0¾d per lb. equal at exchange 1s 7 13-16ths d to annas 10½ in Calcutta. The quality of the manufacture, which was good at the commencement of the season, fell off later on, and on the whole has been very disappointing. *Expenditure.*—The total outlay for the year was estimated at R2,35,000 and the actual expenditure was R241561-1-8. This increase occurred in the garden expenditure, and was due principally to a larger outlay on account of buildings than was estimated for in the beginning of the season. *Profit and Loss Account.*—The balance standing at credit of this account is R10,184-6, which, added to the estimated profit for season 1884, gives a total of R44,365-7-10. This sum is sufficient to provide for payment of a dividend at the rate of 5 per cent on the paid-up capital, and the Directors now ask the shareholders to give them the necessary authority to declare dividend after realization of balance of crop. *Estimates for* 1885.—The estimates for the current season are :—

EXPENDITURE—		
At Garden	...	R1,60,000 0 0
In Calcutta	...	R 83,000 0 0
		R2,48,000 0 0

in addition to which there will be an extra outlay of R8,000 on account of permanent buildings. The Calcutta expenditure provides for the importation of 250 Bengalee coolies. The crop is estimated at 6,350 maunds good Tea.

The Managing Agents of the Darjeeling Tea and Cinchona Association, Ld., have issued their report for the year ended 31st December 1884. The outturn of Tea was 717 maunds, which realized an average price of As. 11-6 pies per lb. The Cinchona bark cropped was 83,957lb. green, which gave 25,089lb. dry, and which sold in London at an average of 9d per lb.; the yield was much better than was anticipated (nearly 3lb. per tree), but being the production of the coppiced trees there was a large percentage of the inferior description of bark. The expenditure amounted to R43,648-6-3 and the working of the season resulted in a profit of R3,678-7-7. The managing agents propose that the credit balance shown in the accounts of R7,974-3-10 should be disposed of by writing R3,636 off block to equalize that account with the capital, and by carrying forward R4,338-3-10 to the current season. The estimates for 1885 are R48,000 for 850 maunds of tea and for an extension of 35 acres of cinchona bark; any barking operations it may be found necessary to undertake this year will depend upon the growth made by the trees during the next rainy season.—*Indian Planters' Gazette.*

NEW DYES, FIBRES, FOODS.

We fancy exploration, to become again thoroughly interesting, must be directed towards things, rather than places; the whole world being searched for things of value, and especially new dyes, new fibres, and new foods. We have always thought that there was nearly as much to interest men in Mr. Fortune's hunt of years for the green indigo—which undoubtedly exists, though he failed to find it—as in any exploration of a new island. The delight of the American who has just discovered a cotton-plant six times as fruitful as the old variety, must be very keen, and not altogether tainted by the reflection—though that is unavoidable—that in such a plant there must be dollars. Just imagine what that man would do for mankind who found a new and vigorous potato, different from the plant which now grows in Ireland, and which is, according to a writer in the *Cornhill*, being propagated by cuttings, which is a single undivided plant, liable to inherit, through all its millions of apparently separate existences, the weaknesses of the original tuber, and liable also to exhaustion, as of old age. It has no children; only a power, so to speak, of having bits of its flesh cut off and planted. It is never renewed from seeds, and so, by all the analogies of Nature, will perish; though the banana, which also is never renewed—and, indeed, in one variety has become seedless—has lasted ages. It is quite possible that there are only two bananas in the world. Or imagine a new and successful cereal,—a real one in the true silica armour, with a head twice as heavy, and grains twice as nutritious, as those of wheat. Why should wheat be the final source of bread? Man got saccharine matters from all sorts of things—grapes, honey and fruits—from the earliest times; but he was old in the world, and had passed through many civilizations, before he discovered the cane and crushed the beet, and so got his present boundless store of sugar. A cereal as fruitful as

wheat and as hardy as rye would change the face of Northern Europe; while one which could flourish on exhausted soil or in a damp climate, might affect the distribution of mankind. The direct gain of mankind from such a discovery might be counted by hundreds of millions; and we know of no law of Nature which should prevent it, and of no guarantee that the cultivating races have exhausted search. They most of them, in the early ages, when they longed for substitutes for fish, and meat, and berries, must have clutched the first edible grass they could find without much hunting for better. Farmers will smile, but there may be grains they never saw. Mincing Lane thinks it knows all about tea, and no doubt does know a good deal; but Mr. Alexander Hosie, of the Chinese Consular service, has eaten and drank a tea which needs no sugar. At least, in the fascinating report which he has presented to Sir H. Parkes, and which has just been published by Parliament to teach travellers how to observe, while recording the result of his hunt after white tree-wax, he says:—"I come now to the last class of tea, the discovery of Mr. Baber. If my memory is not at fault, he was regaled by a priest on Mount Ormei with tea possessing both the flavour of milk and sugar. It may have been in the very temple on the mountain-side in which I am now writing that Mr. Baber was agreeably surprised. At any-rate, I am sipping an infusion which is without doubt sweet, and which is declared by the priest to be brewed from a naturally-prepared tea-leaf. It is a large dark-brown leaf, and is very sweet when chewed. The people at the bottom of the mountain, whom I first questioned regarding this tea, asserted that the leaves were sweet because they were first steeped in molasses; but the balance of evidence, as I have since found from extensive inquiry, is against any such artificial preparation. The tree is said to grow in only one gorge in the mountain, whence the leaves are brought for sale." What will Mincing Lane give for a shipload of that tea, tho very existence of which, till drunk and eaten, the dealers would have regarded as a solemn joke? Men are wise about silk-culture in Italy and Southern France; but they do not know, as the Chinese told Mr. Hosie, that the mulberry-leaf is too strong food for baby-silkworms, and that the wretched little insect, if you want plenty of silk, should be fed-up in earliest infancy on the leaves of a silkworm thorn-tree, fifteen feet high, unknown to Europeans though Mr. Hosie found it everywhere in Szechuen, growing by the roadsides, and as hardy as the thorns, of which it is a variety, usually are. How much difference in annual cash-earnings would the importation of that thorn make in Lombardy? Why should not the Governments, which so steadily map out the seas, even combining to do it, institute a patient and exhaustive search for new grasses able to produce flour, and new vegetables fit for eating? They might not produce many Mr. Hosies, who, if the Members of Parliament read his report, will very soon find himself as well-known in London as any popular author; but they also might. The men like Mr. Fortune and Mr. Hosie, the men whose observation nothing escapes, are not rare among botanists, and would need but little encouragement to carry on for years a persistent inquiry which, if carefully limited to defined objects, would almost certainly produce some considerable result. The work, it will be said, is one for Societies; but it seems a pity to waste the great resource which Governments possess in the wide distribution of their agencies, and in their power of carrying-on their enquiries without reference to time. There will be a Legation at Pekin and Lima, and Jeddo, and Teheran, a hundred years hence: and one official inquirer who records everything, and is replaced when he departs, and is always protected and treated with civility, can, in that space of time, accumulate much knowledge, and will cost but little money. It is organized and protracted inquiry, not a mere spasmodic effort, that we want to see, and that will benefit mankind. Let the Societies hunt for their rare orchids, and plants with lovely blooms and all manner of scientific novelties, and let the Governments promote the search for prosaic things which the ordinary inquirer will neglect. We shall find no new edible animal, we fear, unless it be some variety of goat which can be bred into fatness and made to yield sweet meat—kid properly cooked, that is, roasted to death, is better than most mutton—but a new cereal is clearly a possibility, and might be worth all the botanical discoveries made since the settlers in Virginia sent home the potato. The late Mr. Bagehot, who was always dropping witty wisdom, used to say that the wildest speculator he ever heard of was the first man who dropped grain into the earth and waited till it grew up, and to regret that his name, like that of the discoverer of fire, and of the first man who mastered a horse, was for ever lost. We think we may venture to say that the name of the man who next discovers a cereal of true value will not be.—*Spectator*, March 7th.

RHEA FIBRE.—"Sugarcane" gives us a paper by H. S. Bergman from the *New York Bulletin* giving the practical results of Rhea culture in the north of France and in the United States, which seem very satisfactory. Full particulars will be given in the *T. A.*

TIMBER PRESERVATION FROM FIBRE.—At a time when our tea-planters especially have reason to be anxious about guarding their tea factories from fire, we call attention to the paragraph on page 851 (for which we are indebted to Messrs. Carson & Co.) giving a very simple and inexpensive way of preserving timber from decay and apparently against fire.

TEA IN UVA.—There cannot be the slightest doubt of the suitableness of the higher divisions of Uva for tea, all the top estates in Haputale with their fine soil ought to give splendid returns, and so with much of Badulla. We learn that tea on the Spring Valley Company estates is growing luxuriantly and altogether on this group there will be a total of 500 to 600 acres of tea planted very shortly, besides 900 acres of fine old coffee kept in cultivation. The hardly-tried proprietors in Haputale West ought to look to tea as, perhaps, the only product that can redeem the reputation of their district.

LIGHTNING IN THE TROPICS.—My experience confirms the remarks of Dr. Von Danekelman in *Nature* (p. 127) respecting the little damage done by lightning in tropical climates. In the plains of India at the commencement of the monsoon, storms occur in which the lightning runs like snakes all over the sky at the rate of three or four flashes in a second, and the thunder roars without a break for, frequently, one or two hours at a time. During twelve years' residence in India I heard of only two human beings and, I think, three buildings being struck, although in parts of Lower Bengal the population amounts to more than 600 to the square mile. I always attributed the scarcity of accidents to the great depth of the stratum of heated air next the ground keeping the clouds at such a height that most of the flashes pass from cloud to cloud, and very few reach the earth. This idea is supported by the fact that in the Himalayas, at 6,000 feet or more above the sea, buildings and trees are frequently struck. I have seen more than a dozen pine-trees which had been injured by lightning on the top of one mountain between 8,000 and 9,000 feet high. In the British Islands thunderstorms are said to be more dangerous in winter than in summer, and such a fact, if true, can be explained by the very thin stratum of air then intervening between the clouds and earth.—J. J. MEYRICK. London, December 19th, 1884.—*Nature*.

Coca Leaves from Ceylon valued at 13s per lb. is the good news Dr. Trimen has to communicate as the result of a trial consignment made by him from the Botanic Gardens. Who are fortunate enough to have coca old enough to begin cropping, of who even have growing plants?

Upper Abbotsford, Lindula, 11th April.—The rainfall for March was exactly 2 inches, of which 1·46 fell on the 28th. Since then alternate sun and shower have helped to maintain the extraordinary flushing powers which tea has displayed up here since December last. I have lately had many kind assurances that the statistics I send are valued, or I would not be presumptuous enough to continue inflicting them upon the public. The following are the figures for the weeks ending 28th March and 4th April:—

Date.	Pluckers.	Leaf.	Avge. per Plucker.
March 23	2	28	14
,, 24	2	40	20
,, 25	133	2,524	19
,, 26	144	3,456	24
,, 27	144	4,204	29·2
	425	10,252	24·12
,, 30	127	3,564	28
,, 31	142	2,828	19·9
April 1	55	660	12
,, 2	25	264	10·56
	349	7,316	20·9

My average green leaf per cooly up to the end of last week for the whole year is 20·17 lb. This past week will more than sustain this high figure, and it is hard to see *when* the bushes are going to take their rest. I hear that some misconception has arisen about my average per acre for the various fields. For instance I am still picking from the cattle-shed field *at the rate of* 1,200 lb. per acre. Of course I do not expect this to continue for the whole year; but the best way I can think of of explaining what this rate per acre means is this. If I can only sustain this average to the end of *this month*, I need not pick another leaf for the next eight months off this field, and yet I should be able to record 400 lb. an acre at the end of the year (*i. e.*, 1,200 lb. for four months equals 400 for 12 months). Again, I must correct another most unworthy suggestion that has been made to the "Senior" on his travels. My coolies are still, many of them, picking their 30, 40, and 50 lb. daily, and a little while ago three or four of them picked from 70 to 75 lb. each. It has therefore been said that these special individuals get their children or other coolies to help them. Now this I can positively deny, for the fields are over a mile (in some cases three and four miles) from the lines, and I myself am in the field almost the whole day, and measure nearly every basket personally. Lastly, to prove that tea from young plants is not included in the 110 acres, I give a memo. from our last Tea Report:—

Total tea made (1885)	...	30,036
Deduct young plants (do)	...	4,999
		25,037

25,037 ÷ 110 acres × 14 weeks = 16·25 lb. per acre per week × 52 weeks = 884 lb. per acre. So that our young plants have given a sixth of the whole yield. Our monthly make and rainfall stand as below:—

	Make.	Rainfall.
Jan. ...	8,617 (let the flush run for 2 weeks)	1·57
Feb. ...	10,692	2·11
March ...	10,479	2
	29,788	

As you know, our Giant Tea Tree was blown down, but the other day Mr. R. S. Fraser of Matale and we measured another tree and found it 28 feet 2 inches *in diameter*.

Poonac.—The advance in the market value of this refuse of the coconut oil manufacture is somewhat remarkable, and not easily explainable. For purposes of export it has steadily advanced in price until it has reached R90 per ton!=R4 50 per cwt. Forty years ago, when this article first came into demand for manuring coffee, the Messrs. Worms bought up all they could lay hands upon at from nine pence to a shilling the hundred pounds; when it fell below nine pence it was employed in the mills as fuel! —Local "Times."

Kansas has not lost faith in sorghum as a sugar-cane. Three regular factories exist in the State, and many hundreds of thousands of pounds of sugar are made annually. About 130,000 acres of cane were raised during last season, yielding over twenty tons to the acre. A machine has been patented which cuts, tops and binds the cane, and the peculiar machinery needed for the proper manufacture of sorghum sugar is fast being brought to perfection, while economy in its use is rapidly being learned. Kansas farmers, therefore, want to see the duties on sugars maintained. —New York *Hour*.

Tea Made from Other Plants.—The *Pharmaceutical Journal* of March 21st contains a paper from Mr. Thiselton Dyer on Tea used by the Circassians made from a plant (*Vaccinium arctostaphylos*) grown on the hillsides in the province of Roum. Mr. Dyer's account together with other papers bearing on the subject will appear in full in our *Tropical Agriculturist*. It seems there are several tea substitutes in use in different parts of the world. Another plant (*Ledum palustre*) yields Labrador tea. This reminds us of the coffee-tea at one time freely made in Java from the leaves of the coffee plant and of similar experiments tried in Ceylon an old Kandy resident, whose name we forget for the moment, and Mr. John Tyndall of Glenloch being credited with entertaining their friends to very refreshing cups of "tea" infused from prepared coffee leaves.

Brazil and Jamaica.—We have been favoured with a letter, dated Jamaica, February 16th, addressed by Col. Reeve, who last year visited Ceylon, to a friend in Colombo. The following extracts which we are permitted to take are of special interest, more especially as from other sources our information seems to point to the near approach of the long-expected crisis in the Brazil Labour Market:—"We have been considerable wanderers since I wrote to you 12th Aug. last from Madeira, having visited Bahia, Rio, &c., then some 11 of the W. I. islands all very interesting, but somewhat triste owing to the depression caused by low price of sugar, coffee and agricultural produce generally. Brazil appears to be in a state of uneasiness about giving freedom to all her slaves within the next two years; the planters declare they must be ruined by it, for when the blacks are free, they will leave the estates and take to squatting on the vast lands of the interior or go to the large towns and sea-ports. The slaves are so brutally ill-treated by the Brazilians that they will not labour as freemen for their old taskmasters. Again there is trouble with the Argentine Republic through encroachment on Brazilian territory which may lead to war, in which case the latter will most probably be worsted, the army being crowded with incompetent officers. A country with an annual deficit of 3½ millions sterling with a revenue of 12 millions only, will not be improved by war even if successful. This island (Jamaica) is no longer an Eldorado to the white man, but it is to the yellow and black man, and if the price of sugar does not improve, a few more years of hard times will clear out the white planters altogether. In some parts labour is scarce owing to the exodus to Colon, and the unhealthy isthmus kills vast numbers of the Jamaica niggers."—Mrs. Reeve, who visited Ceylon with her husband, wrote a poem on "The Ruins of Anuradhapura" which will be remembered in the *Observer*.

SILKWORMS.—There has lately been cultivated in Spain a new silk-worm, *Attacus Pernyi*, the peculiarity of which is its habit of feeding on oak-leaves. It is described as hearty and fecund, producing two crops of eggs every Summer, and making cocoons much larger than those of the mulberry-feeder. The silk, when spun, is very strong and handsome. Near Port Mahon great success has followed the experiment of raising these warms on trees in the open air.—New York *Hour*.

VEGETARIANISMUS.—The *Saturday Review* sums up the vegetarian controversy as follows:—All we are concerned at present to maintain, and to support by the practically unanimous consent of sane men, is that animal food is, in a healthy, hungry, human stomach, the most powerful as well as the most rapidly active ingredient in the available ordinary dietary. We also desire to point out the change of front on the part of the vegetarians, whose cry now is that their aliments are stronger, instead of weaker, than those of the meat-eater. This is no longer a mere heresy, to employ the word in a loose sense; it is an acute mental disease; it is, to coin a term, Vegetarianismus.

DIVERSIFIED INDUSTRY is the salvation of a country, diversified farming the safeguard of its agriculture against distress. Any man or community that depends on a single industry is sure to have "hard sledding" some of the time. But with varied products he may have more than one string to his bow. An illustration of how diversity aids the entire community is in the following case: "A farmer on Russia River, California, ten years ago owned one hundred acres of wheat land, from which he derived an annual profit of $1,000. He cut it into five-acre tracts and sold it to hop and fruit growers. Now the same one hundred acres supports eleven families, and yielded this year a profit of $32,000, a single acre producing $600 in plums."—*Exchange*.

VINE GROWING AND THE PHYLLOXERA.—From an interesting paper in the *Journal* of the Statistical Society, we have reassuring information about the checking of the Phylloxera in France. The effect altogether had been to diminish the area under vineyards by 1,400,000 acres, and the average annual production by 350,000,000 gallons. The price of French common wines rising from 1s 10d per gallon in 1876 to 2s 9d in 1881. Many thousands of acres of vineyards destroyed by the disease have been replanted in a more sandy soil, the American vine being substituted, while various remedies, sulphur, submersion, &c., seem to have helped to stay the progress of the disease. Details will be given in the *T. A.*

AMONG THE SOURCES of Petroleum for commerce, Venezuela has long been neglected. All alone the base of the Cordilleras, between the Catalumbia and Zulia rivers, are innumerable fountains of petroleum of excellent quality. Near the confluence of the rivers Tara and Sardinarte, is a sandy space, where are found several cylindrical holes, from which streams of hot petroleum violently gush, causing a noise like a locomotive throwing off steam. The forest thereabouts, called El Inferno, is cool with oil vapors. Nearly six thousand gallons of oil are discharged daily, but it is mingled with water and re-absorbed as it falls into the loose calcareous ground. In various other parts of Venezuela oil is found and gas-wells exist. The "pitch-lake" of Trinidad is allied to this phenomenon, and has long been well known. This lake has an area of about a hundred acres and occupies a cavity of unknown depth in a swampy plain. The bitumen is porous and only slightly flexible—never plastic—yet when a cart-load is dug out of the surface, the hole fills up in a short time. The Government leases the privilege of digging this asphalt to three firms, who, together, export about fifty thousand tons a year, the larger part of which is sent to the United States. —New York *Hour*.

MORTGAGES IN BRAZIL.—How does this read from a country that wishes to attract immigration;—"The Bank of Brazil alone has mortgages on 636 plantations; these 636 men hold, at least, 53,760,800,000 square metres, at the low value of the surveys worth 53,552,955$740." *Gazeta de Noticias*. Feb. 12. And still they are not happy! —*Rio News*.

THE CHEAPEST AND BEST INSECTICIDE.—M Pasteur states that bisulphite of carbon is the cheapest and most efficacious of all antiseptics, and that it is also the best insecticide known, especially in tropical countries—please note that. It costs but the fraction of a penny per pound to produce. In France upwards of eight million pounds of it are annually used to prevent the ravages of the phylloxera. It is said to be capable of such purification as not only to lose its objectionable smell, but to become almost a perfume.—*Dr. Taylor's Science Gossip in the "Australasian."*

THE SILK-PRODUCING ATLAS MOTH OF CEYLON is the subject of interesting notes by Alfred Wailly in the *Journal of the Society of Arts*, which shall be reproduced in full in the *Tropical Agriculturist*. Mr. Wailly received from a lady and gentleman in Ceylon in September last, the largest proportion of live cocoons ever got from a tropical country; the larvæ had been reared on growing cinnamon trees. The possibility of establishing a valuable industry among the Sinhalese people ought to receive attention from the Director of Public Instruction.

THE TOBACCO plantations of Southern Hungary are threatened by a terrible pest, viz. the so-called wire-worm, which differs from the ordinary tobacco-worm, inasmuch as it enters the stem of the plant just above the root and then works its destructive way right up to the flowers. Plants thus attacked yield no tobacco whatever, as the leaves turn yellow and fall shortly after the worm has attacked the stem. The tobacco-worm merely attacks the root. The large plantations of Maslak, which are celebrated for their excellent produce, have been nearly all destroyed this year by the wire-worm, while in other districts the tobacco-worm has done much damage —*Nature*.

NEW PRODUCTS AND OUR HANDBOOK.—A planter in a district at a medium elevation writes:—"Even your elaborate table of 17 columns does not satisfy estate requirements at the present time. I have filled in the columns approximately, but I would be sorry to 'bet a sixpence' on their correctness even with this reservation. The total acreage one can swear to, but when you ask for details, you are giving us a regular puzzle which I am not inclined to handle. On the last mentioned estate (above) 6 products are mentioned, but there are more though not in quantity, such as Liberian coffee, yams, sappan wood (3 bushels seed planted), coconuts and Indiarubber. I am thinking of applying to Government for a grant-in-aid, and to offer to open the place to the public as a garden. I believe it would pay both parties, especially the proprietors."

EMANCIPATION IN BRAZIL.—The Emperor of Brazil, in his speech from the Throne on the 8th March spoke as follows respecting the abolition of slavery in Brazil:—The present extraordinary session has been decided upon through the necessity of resolving on measures regarding the Government Bill that had been framed for the purpose of gradually abolishing slavery in our country, in consonance with the wishes of all Brazilians and in such a manner as to call for the least possible sacrifice and to cause the least embarrassment to the productive power of the country. You will certainly respond to that need with the greatest concern. In your wisdom you will moreover acknowledge that it is of the utmost importance to devise means that shall insure that tranquility in the country which is necessary in order that the substitution of the slavery element should be fully completed. —London *Times*.

Correspondence.

To the Editor of the "Ceylon Observer."

EXPERIMENTS WITH SIROCCO AND JACKSON'S HAND ROLLER.

Theberton, Maskeliya, 3rd April 1885.

DEAR SIR,—I noted in your issue of the 28th ultimo a letter from Mr. C. A. Hay of Blackwater, Nawalapitiya, on tea drying by Siroccos. I note he got 30¾ lb. made tea per hour from No. 710 old style Sirocco, with charge of 9 lb. fermented leaf per tray. I have just made a careful experiment with mine, No. 637, old style, with a charge of 7 lb. fermented leaf and a mean temperature of 283°. I got 34 lb. made tea per hour. (I find that I get more per hour with a 7 lb. charge of fermented leaf per tray than 9 lb. or more.) I never turn my tea, only level tea as the third tray is drawn out before placing in fourth slide.

I promised you the results of Messrs Jackson's hand tea roller made by Messrs. John Walker & Co., Kandy, in January last.

This roller cost R475 nett. It is fitted with pulleys, circular cross action bars of box, also 4 on each side under base sliding plate of table, which decidedly makes it work lighter, as I found, by trying it at first by mistake without the pulleys. Since I have had the machine I took off the hopper fixed on top of box and deepened the box 6". The original size of box when received was 14½" high, 16½" wide each way; increase 6

present size of box 20½" × 16½". (The measurement given is outside; the correct for inside is 19½" × 15½" × 15½".) The box as first received rolled about 50 lb. withered leaf; now it will roll 85 lb., viz., experiment on 3rd April 1885:—1st roll 85 lb. withered leaf in 1 hour; 2nd 76 lb. withered leaf in 1 hour; or 161 lb. in two rolls in 2 hours, or 229 lb. green leaf in 2 hours. This was rolled by 4 coolies, 1 cooly tending, total 5. On 19th March, it rolled 566 lb. green leaf in 5 rolls with 6 coolies. On 2nd April, 419 lb. green leaf in 4 rolls with 5 coolies: that is 4 coolies rolling, 1 cooly tending leaf. When the quantity of leaf requires over two rolls one or two coolies extra are taken on to spell the others.

I feel sure when this machine is connected to water power it will roll in half-an-hour or three-quarters of an hour the same quantity of leaf better than with hand power in one hour. I would note that the leaf even with the large quantity of 85 lb. was very well rolled—quite as well as done by the Universal, from which so far I have only been able to get from 50 to 60 lb. of leaf well-rolled.

I have deepened the box of the Universal 6", but as yet have not been able to see how it acts, as I have not water sufficient at present to work it. When I deepened the box of the hand-roller I increased the weights by 7 lb. each side, or 15 lb.

I will let you know how the Universal roller works with the increase in size of box as soon as I have water sufficient to work it—streams are lower this year than ever I have known them before.—Yours very truly,

T. J. GRIGG.

P.S.—I have made Jackson's sifter do everything. Never use a hand sieve. I have additional sieves to fit in on top, deck on deck, in fact a four-decker. It does its work very well indeed: takes both dust and flat tea out etc., etc., etc. What will Jackson say?

Theberton work of Sirocco No. 637 in one hour from 10-30 to 11-30

Time of trays put in Sirocco.	No. of trays.	Time of trays dried.	Temperature.	Remarks.
10-30	1	10-45	270	Each tray had 7 lb. of fermented leaf.
10-30	2	10-50	up to fall to 300	
10-31	3	10-55		
10-31	4	11-		Temp. of Sirocco did not exceed 300. Sirocco fired for the hour 34 lb. dried tea.
10-47	5	11-5		
10-51	6	11-10		
10-54	7	11-15		
10-58	8	11-20		
11-04	9	11-25		
11-09	10	11-28		
11-13	11	11-30	280	

77 lb. fermented leaf made 34 lb. tea in an hour,

Note.—In a trial I had on the 2nd I got 86 lb. fermented leaf done in the hour, but the 77 lb. in this trial was more carefully done. T. J. G.

CACAO CULTURE IN WESTERN DOLOSBAGE AND ITS ENEMIES.

Western Dolosbage, 6th April 1885.

DEAR SIR,—At last I have found out the animal which destroys so many of my cacao pods. I notice that some of your correspondents have been afflicted the same way, and, as they may have been as much in the dark as myself as to the brute which does the damage, I shall make known my present knowledge. The animal is the "Kola-vedda" of the Sinhalese, the "Mara-nayi" (tree dog) of the Tamils. I do not remember the scientific name, though your Senior mentioned it when round this way.* The

* The Sinhalese name enables us to identify it with the *Paradoxurus Zeylanicus*, and "J. D." and other cacao planters will like to read the full account given by Kelaart:—"PARADOXURUS ZEYLANICUS *Schreber.*

The golden Paradoxure—Coolla-Weddah—*Sing.* Syn: Martes Philippensis—*Camel.* Viverra Ceylonica—*Pallas.* V. Ceylonensis—*Bodd.* Paradox: aureus—*F. Cuv.* P. Philippensis?—*Temm.*

Head elongated, muzzle rather short, blackish. Lips black externally, ears small, dark brown, hairy externally, and almost naked on the inner surface. Whiskers white, long and rigid. A few long rigid grey hairs on the superciliary region. Colour of head and legs dark brown. Upper parts of the rest of a golden brown colour. Beneath paler. Fur dense, short, moderately long, glossy.

Three inconspicuous brown dorsal streaks, diverging and terminating on the crupper. Some very indistinct brown spots; seen only in some lights. Tail long, cylindrical, tip rounded; lighter coloured than the body. Limbs darker brown, soles blackish, nearly bald to the heel. In females an orbicular flat glandular naked surface surrounds the vaginal entrance. Two pairs of mammæ, the fur round the posterior pair of a reddish hue.

A full grown female measured.	Ft.	In.
Head and body	1	7
Tail	1	3½
Head	0	5
Breadth of head, at vertex ...	0	3
Height, at the shoulder ...	0	8

Stomach, 5½ inch, long; small intestines, 10 feet; large, 6 inches; cæcum 1¼ inch, abruptly terminating in an acute point. Kidney 1¼ inch long, and ¾ inch broad at its inferior part, and ½ inch broad at its superior termination. Stomach with a distinct pyloric portion.

Geographical Distribution. Philippine Islands? Ceylon. Specimens have hitherto been received from the highland districts, and from the South and West Coasts. Those from the mountains, are frequently larger, and of a darker golden brown colour. A blackish brown variety has also been seen at Nuwara Eliya which we shall distingnish as VAR.—*fuscus.* (*Paradoxurus montanus, n. h.*)

Smaller than the generality of the above ordinary variet The fur of a darker fulvous brown, with terminal third of hairs of a dark beetle brown colour, giving a uniform rich dark brown surface colour to the animal, which seen

mischief is done only at night, and, has been a cause of much anxiety and expense, and though I have employed night watchmen, changing them frequently owing to the poor result of their vigilance, I could not discover the depredator till a Sinhalese "yakko" hit upon a successful plan. He made a roughly-covered lamp attaching it to his head, inside this was placed the paste of "kekuna" nuts which afforded the light; with this "rum" fixture he dodged amongst the cacao trees and the first night succeeded to my great satisfaction, in shooting two large fat male "Kola-veddas." No doubt, they were attracted by the light upon the man's head, and he being on the *qui vive*, if he does not actually see the body of the animal (for he chooses a dark night), he notices their glistening eyes watching him, lets drive and our rapacious friend licks the dust. The body is about 16 to 18 inches long and tail about same length, hairy and of a mouse colour, height about 9 inches and weight 7 pounds. The head is fox-like.* For its size, an ugly customer, with sharp teeth and claws, just the sort of brute to do a wholesale and retail business in the cacao line. It tears off half of the lower portion of the husk of the cacao pod and swallows the seeds "holus-bolus," afterwards leaving them as a "santosam" on the rocks round about, the same as monkey coffee. I opened up the animals and found them stuffed inside with cacao seeds; no wonder they grow fat and I thin! What more evidence is wanted? An edict has gone forth. Death to the "Kola-vedda" Slay and spare not! I have suffered serious loss, but now, knowing the enemy I have to deal with, I feel that I am in a position to "confound their politics and frustrate their knavish tricks." Bats also attack the pods, making a small hole in the side of the pod; in this case the seeds are dropped quite close to the spot, but the loss arising from this cause is trifling compared with the other. I think cacao is favoured above other products with attacks from insect and animal pests; but, for a' that, and a' that, it is a very interesting cultivation, and I have no doubt will prove a paying one in suitable situations, for it is by no means so cosmopolitan as our great stand-by tea.

The north-east monsoon is going out like a lion, making up for lost time no doubt. We can now cry: "Hold, enough." The soil is thoroughly saturated and all vegetation is flourishing.—Yours faithfully, J. D.

---

in some lights, throws off a few still darker shades or very inconspicuous spots; no trace of dorsal streaks The tail paler, with a rich golden-yellow subterminal ring, which in the dried specimen has become partly albescent.

Head and body ...	...	1 *Ft.*	7½ *In.*
Tail ...	...	1	5
Head ...	...	0	4½
Height at the shoulder	...	0	7

Stomach 4½ inches. Small intestines 7 feet 1½ inches. Large intestines 6½ inches. Cæcum 1¼, pointed.

If our recollection of the golden Paradoxure in the British museum is correct, we do not think our Ceylon animal identical with it. The latter is a darker animal, and the dorsal streaks are more evident on it. Mr. Gray will soon have an opportunity of deciding, as we have sent to the British Museum our best specimens.

The golden Paradoxure appears to be a more frugivorous animal than the Palm cat (*Paradoxurus typus*.) Their habits are alike, nocturnal and arboreal. In all the individuals of the former species, examined at Nuwara Eliya, the stomach contained Cape gooseberries (*Physalis Peruviana*) which grow there now, in great abundance; and only one, had the remains of animal matter in the stomach. When young they are tolerably docile, but as they grow up their natural ferocity returns.—Ed.

* "J. D." should send the skins to the Colombo Museums (2).—Ed.

[In reference to our correspondent's difficulty, Mr. W. H. Wright suggests the following means of catching the *Paradoxurus*:—"Have one good-sized cage rigged out in which you enclose and keep safely a few fowls. Attached to this, or close to it have another one made in which you put a sick fowl that you mean to sacrifice. Leave the latter cage open at night and your enemy will prowl round the fowls till he gets at the victim and sucks its blood out. The next night, or as soon as one fowl has been tasted, leave in the exposed cage a trap, and you will be sure to find the fellow caught in it before morning. Continue the same experiment night after night, and you will clear the place of the *Paradoxurus*." The entrance to the fowl-house might be a trap door.—Ed.]

NORTH BORNEO (NEW CEYLON) AND THE DISCOVERY OF GOLD.

Kandy, 8th April 1885.

Dear Sir,—As some of your readers have written to me for information regarding gold in Borneo, after perusing my memorandum on that precious metal, which you were good enough to publish in your paper, I trust you will not think I am trespassing on your good nature in asking you to publish such of the information I now send you as you think desirable.

You will be glad to learn that our old friends Messrs. Von Donop and Callaghan are once more in New Ceylon, the one acting as Private Secretary to Governor Treacher, and the other Assistant to the Colonial Secretary, Mr. Malcolm Brown.—Yours truly,

W. D. GIBBON.

(*Extract from "North Borneo Herald" dated 31st Dec. from article entitled* "1884.")

In the way of minerals the event of the year has been the verification of the reports of the existence of gold in the Segama river district. On the last day of October, Mr. H. Walker, Commissioner of Lands, started on an expedition in the river with some Sarawak Malays who had brought in a small quantity of gold to Sandakan. He was only three days on the field but reports that he searched at thirty or forty different places from near its mouth (the Bilang river, a tributary of the Segama) "to a point two or three miles up the river and found gold at nearly every trial, generally in small distinct specks, large enough to gather with the fingers, sometimes larger. river worn gold, and always in conjunction with a black metallic dust and iron or copper pyrites. The rocks met with were granite, gneiss, quartz, felspar, basaltic limestone, jaspar, porphyries, red sandstone." We quote from Mr. Walker's report which is before us. It happened most fortunately that H. M. S. "Pegasus" was in harbour when Mr. Walker returned to Sandakan, and advantage was taken of the presence on board her of the Reverend Father Julian Tennison Woods, who has frequently been deputed by the Australian Governments to make reports on geological matters, and the following opinion was given by him: "No. 1 shotty alluvial gold with very little silver, apparently derived from alluvial deposits, and should say if the proper leads were discovered would be very rich; I should recommend trying beds of shallow rivers and small streams. No. 2 seems to contain a fair proportion of tin ore; would recommend a trial smelting."

The advent of the N. E. monsoon with rain and heavy weather on the bar precludes further operations for the next one or two months, after which doubtless the investigations will be resumed, and, should tin, as well as gold prove to be in quantity, we shall have a very different report to make on the country's progress this day twelve months.

Nothing whatever is yet known as to the terms on which the Company will allow these minerals to be worked; whether they will keep them in their own hands, lease

them to a European or Chinese Company, or allow individual Chinese and Malay miners to work on the fields, as in Sarawak.

It appears to us, that if the fields prove sufficiently rich, the Government could not do better than adopt, with necessary modifications, the Queensland Gold Fields Act of of 1884, and the Mineral Lands act of 1882, in force in the same colony, which are fully described in Mr. C. S. Dickson's paper on "The Mineral Wealth of Queensland" read before the Royal Colonial Institute in March last.

One thing is certain, we think, and that is, that the probabilities are that the mineral wealth of this country will be best developed by Chinese labour and even by Chinese capital. The experience of the protected Malay States as regards tin tends to prove, so far at least, that, where Chinese companies can make fortunes, European companies may prove complete failures. For the ordinary Australian digger there is no field here—the tropical climate with its consequent fever, when much exposure to sun and weather has to be borne, is altogether against him, and this should be thoroughly understood. It is melancholy to reflect that the late Mr. Frank Hatton was on the eve of discovering the Segama gold fields when he met his death by accident on the banks of that river.

On the West Coast, at Baugney, chrominm, copper and arsenic have been found; in the neighbourhood of Tamboyukam, near Kinabalu, a silver ore and pyrites; a sample of native copper brought in by the late Mr. Witti is now in the London Office and it is said also to exist in the Paugalau river district a branch of the Padas. A rich sample of galena and silver, yielding on assay 115 ounces of silver to the ton, has been picked up by a native near Mumpakul, now in our territory, and a similar sample has been seen at Suyam Lawass, also in our territory, the natives averring that quantities can be obtained up the Bukaw river. Samples of plumbago were years ago brought by natives to Labuan, but it is not remembered from what district, though Putatau is supposed to have been its source.

The minerals ascertained to exist in Northern Borneo are gold, silver, copper, chromium, tin, plumbago, lead and coal. Antimony and cinnabar are reported. What is now wanted is a thorough examination of the known mineral districts by a practical geologist. Mr. A. H. Everett has an agreement with the Company authorising him to prospect a certain portion of the territory and perhaps no better man could be found for the work, but his time is not at his disposal and his own Provisional Brunei Mining Association has the first claim on him. If only the Company could engage the services for six months, during the dry season, of a gentleman with the experience of Mr. Robert Jack, the Queensland Government Geologist, all doubts would quickly be set at rest, and we should then at last be able probably to say the final word on North Borneo minerals. Is it beyond the bounds of possibility that the Queensland Government should consent and Mr. Jack be willing to lend us his services for a short period? The matter is one of great importance to the country for, as has been said with regard to Australia—what was South Australia but in a state of insolvency before the discovery of copper?—what was Victoria before the development of the gold fields? what was New South Wales even before gold era? How wonderfully these colonies have been awakened under the influence of such discoveries. The mining question is of the utmost importance. Mines develop commerce; they bring population and a demand for farms; they originate towns, with all the high civilization attending them.

IN SEARCH OF GOLD.

(*Extract from Report in "North Borneo Herald" of the 31st December by Mr. Henry Walker.*)

"Gold has been found" was the news I received one morning last October when I arrived at the offices in Elopura It appeared that a party of Sarawak traders, five in number, had returned from the river Segama and had brought a sample of gold. There was not much, but it appealed to the imagination. It was gold, and the excitement grew while future possibilities were suggested. The result was that I was requested to visit the place in company with the Sarawak traders and verify their discovery. They had been assisted therein by a headman on the river who had shown them where to work, but it was Mr. Pryer, the Resident, who first suggested to them to visit the river and discover whether gold existed or not—the inducement being the Government reward of $500 on the discovery of a mineral, one hundred of which is due on discovery and four hundred when the mineral is worked. Their first visit was in February but the rains prevented them working in the river bed; they returned in July and obtained the sample brought on 11th November. There is little chance of getting gold if the water does not fall. The Sungei Bilang is sixty feet wide: the jungle nearly meets overhead, sometimes doos, and without the sun it is a gloomy spot. The Sarawak men are in the hut they made before, which only required new kajangs. They are now putting handles to their tools. My men are busy on their own huts, or on mine which is to be nine feet by six.

The water is very cold, and it was 10 o'clock before the men got to work. They said it was impossible to work at the old spot, there was too much water; so they tried up the stream on a bed of single. They removed the big stones collecting any grit that adhere to them, which they say is often rich in gold, and the top stones once away they collected everything and placed it in their pans—large wooden dishes, thirty inches in diameter with a pit in the centre, very good for the purpose. The result of every pan was a small quantity of black dust, which I am preserving, and almost always in the black gleamed a speck of gold. Where does it come from? One piece is of appreciable size, as large as a grain of rice, but thin and water-worn. There were five men washing, and each was equally successful in finding gold, not in dust, but in small pieces. They washed for two hours, and I was glad they gave up as I could see they were very cold.

I went up the Segama this afternoon to see if there were any hills and came across limestone on the true left bank but nothing further of note. Searching for orchids I raised a little mouse deer, which scuttled away from its lair at the root of a big tree. This is first game I have seen. The wet weather renders it unnecessary for game to come to the river to drink, and my men say a flooded river frightens game away. We have seen nothing but a few alligators and the one rhinoceros mentioned 12th November. We went up the Sungei Bilang: unfortunately it rained a good deal in the night and the river is pretty full, too much so for midstream working, and we have to content ourselves with working the sides. The stuff is too new for any good results. Still at each place we found gold in specks, brilliantly discernable against the black metal accompanying it. No dust—where does that go? A fine day and pleasant working: we did not get back till 4 o'clock, very tired. The jungle is full of a tree, called Ankaug, whose nut yields soil and which the Resident asked me to look for. The oil used in place of coconut oil and is much more valuable. I have given orders to collect a quantity. On the right bank of the Sungei Bilang I saw a tree called Tappang by the Sarawak men, a bee tree, ten feet in diameter at twenty feet above the ground. I believe this would be a big tree in any part of the world. The timber on this river, Segama, runs very large and increases in size as we progress inland.

13th Nov.—The river is much lower and the men set to work near their old spot, and found gold again. They say the river was lower on the former occasion, which I can well imagine as when they stoop to fill the scoop with dirt they buried their shoulders in water. I got my specimens of stone together: they include water-worn granite, like grey Aberdeen, gneiss, slate, crystalline sandstones, jasper, porphyries, serpentine basaltic limestone (water-worn) and coral limestone. As I write their names I cannot help speculating on the possibilities of the future.

14th Nov.—Got away early and found the river fuller than when we came up. At the big fall, Tabanat, we got out to lighten the boats, but did not remove the baggage. Going down the falls was exciting work at first, but there are so many of them they are becoming less so; besides which, as we progress, the waters are becoming quieter. The country we have passed through has been fairly flat, much occupied by natives in days gone by. I feel thankful we started, and that we have had a fine

day as we could hardly have some down safely in the rain. As it was we had some narrow escapes, and, had the rock-ripples been hidden by falling rain, we should probably have come to grief. I stopped a few times to chip off a bit of rock and pick up bits from the single.

15th November. The 16th day. We left at 6-45 p.m. Last night we had a little rain, but nothing that would account for the rising of the river which rose rapidly from the time of pitching our camps until this morning. In the night time I heard the men shouting, and on inquiry found they were moving higher up the bank, and this morning I was awoke by the noise of a falling tree and cries. A dead tree had fallen across one of the huts striking Nacoda Budjang, the head of the Sarawak traders, on the the back of the neck. He was sitting up smoking a cigarette, waiting for daylight, when the tree fell. The day was just breaking, and after a little I was able to examine him and was glad to find no bones broken, but he was almost insensible. I could do nothing beyond giving him my pillow and seeing him laid in the boat as carefully as possible. Immediately after starting we entered a gorge. Hills on both sides for about seven miles—not high, perhaps 200 feet above the river, but tolerably steep, and sandstone rock appeared on the bank. If the future road has to follow the river this portion will be expensive. At the limestone caves I stopped and examined the face of the rock carefully for fossils. To my delight I recognized a coral similar in appearance to one now existing in these waters, but in attempting to break it off I was unsuccessful. I however obtained some pieces with well marked fossils and had to be content. The face of the cliff looked particularly white and bold today, so different from the Gomanton hill, which might be taken for sandstone from its colour. This rock resembles white marble, at a little distance. At the Dusuns' campong we stopped to pay Palar and Uli for coming with us. Paid them in fish and salt. The old men left by Gomba in charge of his big boat (and its contents) had done very well and had a lot of beeswax in nicely made-up cakes. So had the man in charge of my heavy boat further down, at Shabauda Pungut's. He had filled the lower part of the boat with rattan cane. What he gave for them I did not learn, but I dare say the result will be profitable to old Gomba.

For three dry fish (perhaps 3 lb.) we got 50 lb. of sweet potatoes! Barter is at times very profitable. I learn that at Palawan one of our traders gives a box of sardines (price 12 cents) for two bundles of rattans. These latter sell in Elopura 50 cents to $1 per bundle according to demand and quality. Sardines are eaten, like caviare, as a relish, and one box would last some time, but, even allowing for that, the price paid is enormous. Truly these people remind one of the old Romans and their predilection for English oysters regardless of cost! They resemble them in other respects too—the toga, the short cropped hair, a fillet of cloth around the head, perhaps with a flower stuck in it, the short sword at the waist and above all in their grandly independent character,

16th November.—17th day. We stayed last night at Shabunda Pungut's campong. I had to give up my small boat to its owner and pay him for the loan in salt, fish, &c., and remove into the large boat. We left this morning at 6-30 and floated rapidly down to Pangeran Kahar's campong. The launch had left on the 9th. We only remained as long as courtesy demanded and resumed our journey. Still fine, and I am half-inclined to regret I did not stay a fourth day at Sungei Bilang; besides our progress has been so rapid that we shall arrive at the mouth before the launch can meet us.

I stopped at Batu Tatak, where gold is said to have been found, and examined the rock. Sandstone at first sight, but appearing above it is a vein of granitic gneiss with chlorite attached. I got a sample, but found the rock very hard to break.

17th November.—18th day. Last night we stayed at the Gold rock. I got specimens—*micaceous schist*—one a gold red the other grey. A very appropriate name from the appearance of the rock, but I am told that gold is never found near this class of rock. We are 81 miles from the mouth; the river is tidal so far and the depth is over three fathoms.

COCA LEAVES FROM CEYLON (VALUED AT 13s PER LB.)

Royal Botanical Gardens, Peradeniya, 9th April 1885.

SIR,—As it has been stated that the few samples of coca hitherto sent from the East were of inferior quality, I have lately sent home a small quantity picked in the Gardens here with the view of ascertaining the real value of the Ceylon leaf.

A pound of fresh mature leaves was gathered; they were dried carefully in a current of dry air under a verandah, the process being finished off in the sun. This was in the steadily dry weather of last February. The leaves lost half their weight in drying. When finished (in 10 or 11 days), the sample was packed in a tin box and sent by post to Mr. T. Christy of Fenchurch Street for report. He has kindly sent the following information which will be read with interest:—"You will be pleased to hear that Mr. Dillworth Howard has tested the coca leaves and finds they contain ·22 per cent of pure cocaïn which is considered a very fair percentage. At present the cocaïn of Merck is selling here at 22s 6d the gramme; therefore, as a gramme of hydrochlorate of cocaïne is produced from a lb. of leaves, this would make the leaves worth in the market at the present time 13s, and leave a large margin for the maker."

This report seems to show satisfactorily that the leaves grown here yield a fair amount of alkaloid, and that, prepared in dry weather without any special precautions, they will travel home in good condition. I therefore lose no time in making Mr. Christy's information public.—I am, yours faithfully,

HENRY TRIMEN.

TEA CULTURE: DISCUSSION INVITED.

New Brunswick, Maskeliya, 9th April 1885.

DEAR SIR,—There seems to be such a diversity of opinion with regard to the treatment of young tea in Ceylon, that I think it would be of great interest to planters if the subject were discussed in the local papers, as there appear to be advocates of two methods one is to keep the stem of the tree, or bush, clean six inches from the ground, by pulling off all suckers and side-shoots below that height; the other is to encourage suckers and everything to grow. The Indian tea planter is undoubtedly in favour of the former, though I believe the *latter* is the general mode of treatment in Ceylon.

I should like to know the reasons assigned by those who have experience in Ceylon, why they should differ in this matter? Does the latter method insure more leaf without injury to the future welfare of the plant, as regards yield and lasting qualities?

I consider this a most important question to be discussed at this time, as there is such a large acreage of young tea now coming on in the island. Those who can give us information on this point, will be conferring a great benefit on their fellow planters, and I trust they will kindly come forward and do so.—Yours faithfully,

A. E. WRIGHT.

HYBRIDIZATION.

Theberton, Maskeliya, 9th April 1885.

DEAR SIR,—I notice a remark on plant improvement by hybridization from the *Queenslander* in the *T. A.* for April.

It occurred to me after reading this article, that some experiments might be tried to hybridize the Arabian coffee with Liberian, that is taking the best samples of each? It is well-known that hybrid Assam tea plants are better than either pure Assam, or pure China, for plucking &c. I should fancy that

the Director of the Government Experimental Gardens might take up such a subject as this and work it out. It is something more than leaf-disease that is killing out our coffee. Could not something similar be expected from the experiment I suggest to what occurred to the apple tree in America? Very many remedies have been tried as regards coffee; surely all is not done, and there is yet an opening for fresh investigation.

It is a pity we so seldom now see the advertisements of useful products for sale or distribution.* The Gardens are one of the sights Australasian and other visitors delight to see.—Yours faithfully.

T. J. GRIGG.

TIMBER PRESERVATION.

Colombo, 11th April 1885.

SIR,—We enclose a cutting from *Engineering* bearing on the preservation of timber. It may be of interest to readers of your daily issue and the *Tropical Agriculturist*.—Yours, &c., CARSON & Co.

[The extract, which ought to be of special value to planters, is as follows.—ED.]

PRESERVING TIMBER.—About five years ago the chemist of a corporation in the United States, wishing to preserve shingles against decay, and also render them incombustible, impregnated them with lime and salt by boiling them in a solution of 10lb of salt and 20lb of lime with 250 gallons (2,550lb) water. Ten bundles of shingles were boiled until thoroughly saturated, the process costing 50 cents per 1,000 shingles. These prepared shingles have been used for roofing purposes, but with and without the protection afforded by paint, and the result has proved in every way satisfactory. Recently some prepared shingles were subjected to trials in competition with ordinary shingles. They were dipped into naptha and lighted, the ordinary shingle burning until consumed, while the flame on the prepared shingle went out as soon as the naptha was burned, and without igniting the shingle. A spark test made by a burning mixture of charcoal, sulphur and saltpetre on the shingles burned the ordinary shingles, but only charred those which were prepared. Exposure to gas flames showed similar resistance to combustion in the prepared shingles. The antiseptic properties of lime upon wood and iron are well-known, the only element of uncertainty being the rate at which such lime and salt deposits in the pores of the wood would be removed by rain storms. The experience of five years shows that this decrease is a slow one, and may be retarded by paint. It is considered that such preparations may be applied more thoroughly to green lumber where the sap cells are still open and capable of absorbing moisture than in seasoned stock, which cannot have so much permeability.

BULKING AND PACKING TEA IN COLOMBO.

13th April 1885.

DEAR SIR,—I have read with interest the letter by "C. W. H." on bulking and packing tea in Colombo. I notice he has omitted a very important point, viz., the additional cost to the proprietor of the handling in Colombo; that it would be an additional source of expense without any equivalent saving or advantage, I think, there can be no doubt. It is obvious there would be no saving effected in material, carriage, or labour on the estate. "C. W. H." says "freight to the estate on tea lead and nails was saved." Was his zinc- or tin-lined case—made probably of one inch boards—lighter than an ordinary lead-lined tea chest? As they were unscrewed in Colombo, it is evident screw nails would have to be carried to the estate to refasten them. Then as regards carriage to Colombo, the fact that only about half the weight of unsorted tea can be put in a chest or case has been lost sight of; consequently more cases are necessary and the carriage on empty cases or shooks of chests nearly double what is requisite when sorting and packing is done on the estate. The only apparent saving on the estate is in sorting, and this is so trifling—less than half a cent per pound—that it might almost be left out of consideration.

There is doubtless some necessity for such a factory to manipulate the tea purchased at local sales, and as these sales become popular and of more importance, sufficient work might be found for one establishment; this would, however, merely be for *bulking and packing*. Superintendents will prefer sorting their tea in the estate factory even when making in quantities too small for shipment.

The empty stores and grass-grown barbacues to be seen in Colombo just now are certainly painful spectacles, reminding us—especially their owners—of the profits of other days, but I trust your able pen will devise some more appropriate use for them than that of repacking tea, which, as will be generally admitted, can be done as well and with less expense on the estate. S.

* It is produced once a month.—ED.

HEAVY CROPS FROM YOUNG COFFEE.

Colombo, 15th April 1885.

SIR,—I have gathered and shipped from coffee in Uva planted during the month of October and November over 5 cwt. per acre at two years old; that is to say a clearing of fifty acres planted, we will say in November 1870, produced 260 cwt. of cured coffee shipped on board ship in Colombo in December 1872. Mr. Byers took several similar maiden crops from Angodde. I have also taken a little under 4 cwt. per acre from a clearing at two years old, and 12 cwt. per acre from the same clearing the following year. I have seen 8 cwt. taken as maiden crop in Pussellawa, but, owing to difference in season for planting and maturing, the coffee was from four to six months older than what we called two-year old coffee in Uva. The largest maiden crop I ever saw was on Hangranoya, W. King's. The clearing was a forest ravine in patana. I forget what the crop actually turned out, but it was over 8 cwt. I have seen gathered from a field of four years old in Uva one cutty-sark from every tree or one box from every four trees, which, at only 1,000 trees to the acre (the ground being rocky), gave 250 boxes or 125 bushels parchment, say 25 cwt. per acre cured coffee, and the field was not then picked; this may seem a gross exaggeration, but I stood in the field myself and saw it picked: the ground over which this large crop was gathered would be about ten acres; the average for the whole estate was about 12 cwt.

Your correspondent asks how much coffee actually set at from one year to fifteen months. In all cases of heavy bearing, the crop actually set would be largely in excess of the quantity gathered as the trees throw it off. I have seen 5 to 6 cwt. per acre small berries under the trees: six or eight weeks after blossoms the trees could not carry the crop set. I should think 5 to 6 cwt. crop set on young trees, say of fifteen months old, not uncommon in Uva some years ago. JAMES IRVINE.

[Mr. W. H. Wright has gathered 4 cwt. per acre off 18 months' old coffee at Peradeniya and in Haputale, and 6 to 7 cwt. from Haputale coffee 2 years old, grown however from fine healthy stumps—all in the good old days.—ED.]

THE TREATMENT OF YOUNG TEA.

Tratatum, 15th April 1885.

SIR,—Where does Mr. A. E. Wright get his authority for saying Indian tea planters are in favour of the plan:—"to keep the stem of the tree, or bush, clean six inches from the ground, by pulling off all suckers and side-shoots below that height"?

The late Mr. Cameron I know was not in favour of this plan, and I have spoken to several Indian planters who did not practise it. In fact Mr. P. R. Shand of Strathellie is the only planter I ever heard of trimming his tea plants in the way described, and that was some years ago. Of course all straggling branches with a downward tendency should be cut off.—Yours truly, EXPERIENCE.

CACAO INSECTS.

Uva, 15th April 1885.

DEAR SIR,—I should be much obliged if you would inform me if the insects which accompany this letter are *Helopeltis Antonii* or not. If they are not, they are at least as destructive as the genuine article *can* be; for they have done and are doing a great amount of injury on several places in this district where cacao is cultivated. They operate on the pods in such a way as to render the latter perfectly worthless, and the cacao trees themselves are also severely affected by these insects.—Yours truly,
E. X. Z.

[Our entomological referee writes:—"Examined and found to be the true *Helopeltis Antonii*."—ED.]

BRITISH NORTH BORNEO.

(From the *North Borneo Herald*, March 1st.)

The Borneo Trading Syndicate.—Under the above title a Syndicate was formed in Melbourne in the latter end of November last, having for its object the inauguration of a regular trade between North Borneo, London and Melbourne in the products of this colony. The chief aim at present is the export of indiarubber, guttapercha and dammar, to be supplemented with ivory, tortoise-shell, vegetable tallow, pearl shell, seed pearls, &c. The President is Mr. John Blyth of Messrs. Blyth & Co., London and Melbourne, who is President of the Melbourne Chamber of Commerce. The expedition is in the hands of Capt. R. D. Beeston, late of the Bengal Army, who our readers will remember was here some eighteen months back on behalf of the Australian Borneo Company. He is accompanied by Mr. E. W. Thomas, a gentleman of considerable experience in New Zealand. Since his arrival, Capt. Beeston has been by no means idle, and has already secured a shipment of indiarubber and dammar, which will shortly leave for London. Capt. Beeston has formed a very high estimate of the products of the country and the ample scope for trade that is opened up to his syndicate, and has already reported most favourably to Melbourne. He is also paying close attention to the hardwood timbers of North Borneo, more especially as regards billion, balow and russok, and feels sanguine as to the prospects of opening up a large trade in hardwood timber with Melbourne, to be used more especially for sleepers, piles, and wharf timbers. He is of opinion that the capabilities of billion for the above mentioned purposes are unsurpassed, and is sending samples to Melbourne, which will be seen and tested by practical gentlemen interested in the timber trade there.

A COUNTRY WITH A FUTURE.

The well-known African traveller, Mr. H. M. Stanley, has contributed to the *Standard* a very interesting statement as to the prospects of commerce in the Congo region; which he has done so much, in connection with the International Association, to open up to the influences of civilization. The boundaries of the Free State, which has been created by the recent Berlin Conference, comprises about 900,000 square miles, and is, therefore, about four and a-half times as large as France. Of this vast area 600,000 square miles are, says Mr. Stanley, of unsurpassed fertility, and the remainder less valuable, but still of excellent quality. The territory includes over 41,000 square miles of lakes, besides nearly 4,000 miles of navigable rivers. The only important interruptions to free passage are the Stanley and Lubelash Falls, and to obviate all obstacles presented by the river it is proposed to construct a railway 147 miles long, of which 52 will run between Vivi and Isanglia, and 95 between Manyanga and Leopold ville. In the first year after the opening, Mr. Stanley believes the railway will pay 20 per cent. It will open up a region containing not less than 30,000,000 of inhabitants. Of the commercial future of the Free State, Mr. Stanley speaks in glowing terms. On the coast line, from Gambia to St. Paul de Loando, every place which offered any promise of trade has been made the settlement of factories, which carry on a trade to the extent of £32,000,000 yearly. The interior must of necessity offer a far larger field. Palm oil, rubber, gums, coffee, copper—already smelted by the natives—ivory, camwood and orchella weed, both valuable for dyeing purposes, palm fibre, and hides are amongst a few of the chief articles of native trade. There are besides vast areas covered with the most valuable timber, such as ebony, mahogany, lignum vitæ, teak, and redwood. All kinds of European vegetables, as well as wheat and rice, will grow luxuriantly, and both sugar and cotton are indigenous to many parts of the country. The railway will bring the interior and its wealth into direct communication with the sea. At first it was almost impossible to get the natives to work for the settlers on any terms. But now, having found that they will be fairly paid and well treated, they are eager to offer their services or to sell their ivory.—*Christian World.*

THE RUBBER cleared in the *Recebedoria* at Pará during last year reached 9,860,157 kilos., of which 835,763 was Peruvian. The exports for December were 646,000 kilos. for the United States and 723,000 kilos. for Europe; stocks on December 31st was 891,000 kilos.—*South American Journal.*

AGRICULTURAL AND HORTICULTURAL SOCIETY OF INDIA.—From Captain F. Pogson, forwarding for examination and report a rope made from the bark of the *Maul Dhun* creeper, which grows abundantly and to a considerable size in the forest. The rope is very strong and is used for tethering cattle, the leaves are used by the *Bunnias* and *Halwais* for packing purposes, and are large and tough. Captain Pogson goes on: "it appears to me, that under culture the young bark would be of considerable value for numerous purposes, including the manufacture of sacking and canvas, while the refuse would answer very well for paper." The plant has been identified as the Bauhinia Vahlii, well-known for the strength of its fibrous bark, ropes constructed of which are used in suspension bridges by the natives. Captain Pogson has been asked to obtain some of the seed for the Society.—*Indian Agriculturist.*

MALACCA.—Unfortunately, the drought still continues. No inhabitant can remember a dry season of this description. Nearly all the wells in the place are empty, except a few of those situated at Bukit China. Wells that have never been known to fail, in the memory of the living, are now dry, and it is necessary to purchase water both for bathing and drinking purposes. The hospital is no exception, and considerable expense is being incurred in providing the necessary supply of water. A very large proportion of fruit trees, both in town and country, have been scorched up, and they have the appearance of having been burnt by fire. The loss occasioned by the withering of fruit trees will amount to some thousands of dollars, which will chiefly fall on poor people. We should be very thankful that the place continues to be healthy. The authorities have taken the precaution of frequently putting lime into the drains, and flushing them. The rain-clouds have frequently collected over our heads during the past fortnight, but the rain cometh not. Singapore also appears to be suffering from drought, but the only inconvenience you appear to be put to is having the water supply cut off two hours per diem.—*Singapore Free Press*, March 28th.

CEYLON PLANTING: SEEING THE TEA GROW: WITH A GLANCE AT CACAO, CARDAMOMS AND OTHER "NEW PRODUCTS."

THE KELANI VALLEY—TALAWA ESTATE—SUGARCANE CULTIVATION ON THE COLOMBO-AWISAWELLA ROAD—BRICK AND TILE MANUFACTORIES—THE LABUGAMA RESERVOIR—EARLY ATTEMPTS AT AGRICULTURE—TEA FLOURISHING IN THE OLD SUGAR FIELDS—CACAO IN MATALE—SHADE TREES—TREATMENT OF LEDGER CINCHONAS—MUST CINCHONA PERISH?—COFFEE SNUFFED OUT BY BLACK BUG. NATIVE COFFEE KILLED BY BUG—EUROPEAN COFFEE EXTIRPATED ON ACCOUNT OF BUG SPREADING FROM IT TO TEA—A CLEAN SWEEP OF COFFEE—CINCHONAS ALSO BEING ERADICATED—ESTATES IN ELKADUWA—A CONTRAST IN CLIMATES—DIFFERENT TREATMENT OF HIGH AND LOW TEA NECESSARY—GROWTH OF TEA IN THE LOWCOUNTRY AND ON THE HILLS—SOIL—THE TAPROOT OF THE TEA PLANT.

In the course of journeyings occupying nearly a month of time and extending over some two hundred and fifty miles distance, I have seen tea growing at every elevation from a few feet above sea-level to an altitude here (Lindula) of six thousand feet, and I can, in describing what I have seen, use only the degrees of favourable comparison, "good, better, best." There are plants growing, as I have said, a few feet above sea-level, but in journeying up the beautiful and fertile Valley of the Kelani—over which, according to Hindu legend, the sun pauses with delight in his diurnal course—the first regular tea estate occurs at the twentieth mile from Colombo on the left of the Ratnapura Road. The property, like so many others in Ceylon, belongs to the ubiquitous "De Soysa." It is called "TALAWA," the beautiful word by which the Sinhalese describe an open glade; so that Talawakele is the forest of the glade or open space, the open space in that case being, doubtless, the flat (comparative flat for Dimbula) chosen as the site of the present temporary terminus of our grand mountain railway. Mr. De Soysa's low-country "Talawa" is doubly interesting, as being not only the first tea estate visible on the road up the Kelani Valley, but as combining three of the great cultures of Ceylon: coconuts and cinnamon are grown on the lower portions of the land, while tea is planted up to the summit of a knoll on which stands a conspicuous bungalow. Neither coffee nor sugar is now cultivated on a large scale in the valley, but patches of both may be seen around native houses. Indeed, the extent to which sugarcane is cultivated in garden plots by the sides of the road at once arrests the attention of the traveller from Colombo to Hanwella and Awisawella, as much as does the series of brick-and-tile-making establishments which exist for the first portion of the way. Deposits of good, tenacious clay are plentiful, but we had proof that they do not extend far beyond the banks of the river, in the fact that, as we passed upwards, we saw a large force employed in digging out clay to be used in a puddled form for closing the leaks in the rocky bed of the Labugama Reservoir, whence Colombo is soon to derive its supply of water. The existence of fissures in the gneiss is, in this case, most unfortunate, and the remedy must involve large expense; for we noticed, that, in order to get at the bed of clay, an enormous superincumbent mass had to be removed of the fertile red mould, over expanses of which in the neighbourhood of Hanwella a beautiful English-like sward is spread. There are few prettier or more "home-like" grass lands in Ceylon. The covering of red soil removed (this red soil being doubtless the form of laterite called "cabook" in its most advanced stage of comminution and decomposition), the clay to be used for puddling and closing up the cracks in the Labugama Reservoir had to be carried a distance of ten miles before being used! It is not only the distance but the ascent of five hundred feet which must render this process very expensive. The work is, in every sense, a great work, and, when it is completed, it will tend to keep Colombo more than ever the healthiest city of the tropics, besides making the harbour even more than at present attractive to shipping. Nearly two years ago, I was able to appreciate the enormous amount of work involved in laying so many miles of iron piping from one of the sub-ranges of "the Peak" to Maligakanda, Colombo, the pipes being then in course of laying. Now, they are hidden from view, except where they are carried across the few tributaries which enter the Kelani in its lower course.

I need offer no apology for this digression in favour of works which will render Labugama more famous than it has already become from being the scene of royal "kraals" or "corrals" where Princes of the reigning British family and representatives of royalty witnessed the capture of the royal beasts of our forests, those elephants to which, according to Hindu belief, all others make obeisance. The reservoir hill with its cleared summit is a conspicuous object from every point in the Lower Valley of the Kelani, which gets gradually dotted over with outlying and more or less detached hills as we go up stream, until around Awisawella and Ruwanwella they aggregate, and are the scenes of a most promising series of tea estates. Having mentioned the sugarcane as grown in patches by the natives, mainly to be used for sucking purposes, the juice being nutritious as well as refreshing, I may as well advert to the attempt made about forty years ago to grow sugar on a large scale in the neighbourhood of Awisawella and Situwaka. In being shown over the tea-covered undulations of Penrith estate by Mr. F. W. Byrde, I was much interested to learn that I was walking over what had once been expanses of sugarcane, a Sinhalese man accompanying us who remembered the first clearing and planting with sugarcane of the land for the late Mr. John Armitage. He also pointed out the site of the bungalow occupied by the superintendent, my old friend, Mr. Alexander Vallance, whose writings made a lasting impression on my mind from the fact that each sentence ended with a note of admiration (!). I met him in 1859 on Kirklees coffee estate in Udapussellawa, when he told me how much troubled his mother and his sister Janet were that he could not regularly attend the services of the Kirk. More fortunate than many others, this honest and prudent man, as superintendent of coconut, sugarcane and coffee estates, was able to save money and retire in the evening of his life to his native country where the services of the Kirk could be easily availed of. I need scarcely say that sugar cultivation was no more successful in the Valley of the Kelani than in the Valleys of the Mahaweliganga, the Kaluganga, the Mahaoya, or the Gintara and Nilganga. But I learned that the experiment near Awisawella resulted in a considerable and permanent native cultivation of the cane from which a good deal of coarse sugar or rathe jaggery is manufactured.

In the old chenas of the once sugar fields I saw tea plants flourishing, as indeed they flourish under all possible conditions if the climate is sufficiently moist. In this characteristic tea differs essentially from cacao, which Mr. Robert Fraser of Matale told me was never tried in Trinidad on old sugar land. Cacao does not desiderate moisture

as tea does, but this comparatively delicate plant requires deep rich soil and shelter from wind, if not in every case shade. To me, whose experience of cacao was its having been blown out of existence within less than twenty miles of Colombo by the winds of the south-west monsoon, it was beyond expression refreshing to see the luxuriant groves of Theobroma (food for the gods) in the Valley of Dumbera, at Wariapolla, at Kawudupelella, and *en route* northwards to the thirty-third mile, where, on the sides of the remarkable, isolated, twin-summited mountain of Arunagala, a promising plantation has been opened. So far, and even beyond, the rainfall is sufficient for cacao, and probably for tea. The richness and the depth of the soil was evidenced in the valley of Matale by the truly enormous size of the primitive forest as well as by the luxuriant growth of the planted shade trees. In Mr. R. Fraser's exquisitely lovely valley of St. Antonio, I first saw worthy specimens of the *Erythrina* known as *Bois immortelle* or *Madre de Cacao*. Nothing which I saw of the "dadap" in Java impressed me favourably—quite the reverse indeed—and when I was in the Dutch island at the latter end of 1881 the planters had transferred their love for it as a shade tree to the luxuriant but brittle *Albizzia moluccana*, the great merit of which was said to be that its leaves hung vertically at night, so permitting *the fall of the dews*, an idea wholly unscientific. This albizzia is really a good shade tree, but its extreme brittleness renders it dangerous to cultivation and even to human life. The somewhat allied tree, the *Inga Saman*, of magnificent growth and lovely acacia blossom, is *not* a good shade tree. Mr. Fraser is enthusiastic about the merits of the *Madre de Cacao*, alleging that, besides its giving shade at the proper time and in the proper proportion, its roots draw up moisture from the subsoil for the benefit of the cacao in droughty weather. This opens up a most interesting question and may largely explain the good effects of the *Sau* tree (*Albizzia stipulata*) on the tea bushes amidst which it is planted in India, seedlings of this tree in nurseries being actually credited with good effects on the tea seedlings in contiguity to them. Is it not possible that the roots of the *Sau* tree and those of the South American *Erythrina* may have the power of pumping up not merely water, but water impregnated with fertilizing matter which the roots have the power of decomposing? Had I known nothing of the *Bois immortelle* beyond the grandly luxuriant trees of a few years old which I saw on Wariapolla covered thickly with leaves as large as those of *Ficus clastica*, I should have pronounced its shade too dense, but, like all the *Erythrinas*, it is a deciduous tree and is said to cast its leaves (valuable as manure) just at the season when the protected culture least needs and can best dispense with shade. One thing is certain: that the *Bois immortelle* is a great acquisition to our list of fine foliaged and flowering trees, a list already so rich. Mr. Ross of Kawudupelella holds that there can be no better shade for cacao than jak, although grown amongst tea its effects on that otherwise hardy plant are deadly. Mr. Ross in clearing for cacao would leave no natural shade. He would make a clean sweep and create shade. Mr. Fraser does not agree with this view nor in the preference of jak to the *immortelle*, and such differences of opinion between experts try "the five wits" of novices like myself endeavouring to learn. Sambo and his master "'sputede" a whole day on one occasion, because the former asserted that sandy ground was good for squashee and the latter agreed with him; but "the converse of this proposition" came under my purview during my wanderings, when two experienced planters had a hot argument over their precious "ledgers," nsf the estate books but the monarch of cinchonas. One held that he had done rightly in lopping off all the side branches from his trees, whilst the other cherished his primary and secondary branches and asserted that, deprived of them, the trees would grow up spindly and poor. The disputants parted "each of the same opinion still," leaving to me the difficult task of deciding. On the particular question of ledger cultivation, I feel inclined to say no more than that where planted by themselves the branches ought to be left on to about the fourth year, when the lower ones can be pruned off and the bark utilized. But, if grown amongst tea, even ledgers ought to be pretty severely lopped. But the general and orthodox view now is, that tea, like the Turk, "can bear no brother near the throne," and that not even stray cinchonas ought to be tolerated amongst the chief new product. This belief is being practically applied, cinchonas going the way of coffee, and I leave readers of the *Observer* to judge how largely the extirpation of the fever trees, in favour of the exclusive claims of tea, is likely soon to affect the export of bark from Ceylon. For myself I can say, that, holding my eyes open during my recent journey from Colombo *via* the Kelani Valley, Dolosbage and "the northern districts," to "the young districts," I was equally impressed with the magnificent groves of flourishing cinchonas, existing in favoured situations and the ruthless determination to make a clean sweep of every plant growing in land intended for tea. Mr. T. C. Owen will, I feel sure, forgive me for quoting his weighty authority. Passing through the old coffee estate of Hatale which he is converting into what will be a fine expanse of tea, I said, looking at the splendid young cinchonas which had been planted over the estate: "It will surely be a sore problem to solve, what to do about these flourishing cinchonas." "Out they must all come!" was the prompt and emphatic reply. So it is, wherever tea has been planted amongst either coffee or cinchonas, and even where the intention and the desire was to preserve old coffee for the sake of a possible "one more crop," the fiat of destruction has gone forth. The process was hastened by the advent of black bug (the first great enemy of Ceylon coffee forty years ago), the scale insect coming to complete the ruin which the fungus had commenced and was carrying on with so much virulence. Coffee, especially native coffee, weakened by repeated attacks of leaf-disease, was in many cases actually snuffed out of existence by the resuscitated coccus plague.

Facing Poodalgodde in Rangala, Mr. E. J. Young pointed out to me in a fine Kandyan township, the seat of a Ratemahatmaya, above the line of the green terraced rice fields, patches of grey skeleton twigs, such, I may remark, as may be seen on an abandoned coffee estate a few miles on the railway below Hatton. What I looked at from Poodalgodde were the skeletons of the bug-killed village coffee, and the willingness of the natives now to work on tea estates—a most important factor in the certain success of the enterprize—is due to the people thus being deprived of the main resource by which they obtained a little money when they wanted it. But in the case of coffee grown by Europeans, *cultivated* and therefore better able to resist the attack of the coccus, the result was largely similar. For, apart from the fact that the growth of tea under the shade of coffee bushes was scarcely at all lateral, but upwards and spindly, it was found that the well-named "black bug" (the brown insect being ever accompanied by a horrible black blight) was spreading from the old coffee to the young tea with disastrous effect. Death to old coffee was there-

fore the verdict, as well as removal of cinchonas. Indeed the result of the experience I have adverted to is, that over large expanses now in the older districts, where tea is superseding coffee, there is no further thought of waiting for one or two crops while the tea is growing, but a clean clearance is made of the coffee, before the tea plants are put in. A striking illustration of this process was presented to me on part of the once grand coffee estates of the Messrs. Hadden, which I remember, under the superintendence of good old Mr. Peter Moir, yielding 11, 12 and even 13 cwt. per acre per annum. Coffee which thus did its duty well in the olden days has been honorably cremated in preparation for the reign of its heir by adoption. Nothing could so reveal the high quality of the soil, from Elkaduwa, where tea seems a continuation of the native rice terraces, up to the calcareous rock of Kandenuwara, than this process of thorough clearing and planting *de novo*. But I need not again draw attention to the great effect in the near future of this clearing process on the exports of coffee from Ceylon, but especially on the figures which will represent the quantity of bark our island will, a couple of years hence send, into the markets of the world. While so many are eradicating cinchonas, no one that I saw or heard of, is planting the fever trees, and the only recently planted coffee I saw was on Pallekelly, where (advisedly, no doubt, with reference to soil, climate and experience) Arabian coffee was grown as shade for cacao, to be removed when a couple of crops were obtained. I need not say how glad I was to foregather with Mr. Hadden on his own domain, old as coffee planter, as also in experience and sagacity, but young and justifiably sanguine as a tea planter. I also must confess to being old in some respects, the proof being that on the occasion in question I was being carried in a mandarin's chair, courteously placed at my disposal by the laird of Wariapolla, Mr. R. S Fraser. I cannot positively say whether, consistently with the occasion, I was shouting to the bearer coolies the "pidgin English" equivalent of "Excelsior!" in the shape of a "*Topside galow*!" but in any case my appearance must have been very *imposing*, for I was evidently taken for the Governor, whom, as is well-known, I closely resemble in physique though not in intellect. It was amusing to notice how rapidly Mr. Hadden exchanged a look of ceremony for one of cordial frankness when I alighted and announced myself as "only the Senior Ed. C. O." We had a delightful evening walk in a perfect climate, which Mr. Hadden has found restorative, up to the ascent of Kandenuwara rock, "sputin'" after the fashion of Sambo and his master as to the assured success of tea and the retrieval of the fortunes of individuals and of the colony by its means. Mr. Hadden, on returning to the colony a couple of years back, saw the fine tea field on Elkaduwa, and at once made up his mind that tea would be a success, even while some interested in the property were doubtful. He at once acted on his conviction, and there is evidence already of the wisdom of his conclusion and course. Of this evidence and of other matters I shall speak in a future communication. That and whatever may follow will be after the fashion of this discursive epistle, information and incidents being dealt with as associations recall them from a memory to which after the first day of formal note-taking I had entirely to trust. When a traveller is verging on threescore and ten, and on his forty-eighth year in Ceylon, he may be pardoned, if he cannot combine incessant movement with regular entries in a note-book. Whatever else I may, for this reason, be unable to recall, however, I can certainly never forget the more than kind reception I met with in my progress from the low country tea estates in the Kelani Valley to those in the higher regions of the mountain zone. My reception in the lower elevations vied with the warmth of the climate, while at the higher altitudes the atmosphere alone was cool.

Out for a walk this morning (April 15th) at an altitude approaching 6,000 feet, in a temperature marked by the thermometer at 56°, and longing for the warmth of the sun's rays, I could not help recalling the contrast of a fortnight ago in the Matale Valley when, at the unearthly hour of 4 a.m. I felt oppressively the exertion of walking *down* hill, in an atmosphere which was simply a vapour bath. Still more striking was the contrast to my noonday walk of a month ago with Mr. F. Byrde up the steep tea-clad sides of the Awisawella estate, exposed to the full blaze of a sun which would certainly raise the mercury in an exposed thermometer to 160°. There is no mistake about the heat in the Lower Valley of the Kelani, any more than of its forcing effect on tea and other vegetation. A visitor here, a few days ago, asked me which climate I preferred, and there could be but one answer, considering the difference between English summer warmth (yesterday's range was from 72° to 54°) and the most fervent heat of the tropics. For pleasantness and salubrity there can be no question as to the advantages of the zone extending from 2,500 to 6 500 altitude. In the lower climatic zone, the compensating advantages are a more rapid and luxuriant growth, where good soil is present, and generally speaking, as regards tea, a stronger flavoured leaf which commands high prices in the London market. All the European gentlemen whom I had the pleasure of meeting in the exquisitely beautiful but fervidly hot valley, in the latter end of March, looked as if malarious fever were non-existent; but I regret to see in the papers a statement to the effect that the attendance at a recent festive occasion was diminished by an outbreak of fever such as must be counted with in all similar regions when the soil is first stirred. As clearing advances and the age of estates increases, no doubt the visits of the mysterious agency we call malaria will become few and far between, exemption from its influence being probably in proportion to elevation, distance from the river and shelter from the north-east winds. It is pretty certain too, that estates in the lowcountry, while forced by the climate into earlier and heavier bearing than those in the loftier zone, will be sooner exhausted and their proprietors compelled at an earlier period to supply the soil with nitrogenous, phosphatic and potassic substances such as Mr. Hughes indicates in his letter just published. In the higher regions, estates, especially opened on virgin soil or on old coffee soil of exceptional quality, will be less exposed to the consequences due to combustion of the soil and its exhaustion from over-luxuriant bearing; although really I can scarcely imagine anything more luxuriant than the growth of tea I have recently seen, in this specially genial, if dronghty, season, up to even 6,000 feet. When the flush can be "seen growing" at that altitude, what must be the rush of growth at 200 to 1,000 feet? It has been stated to me that as a matter of fact the yield of tea on many lowcountry estates has been disappointing. Wherever that is the case, the soil is probably at fault, and most likely in its mechanical condition more than in its constituents. I have already expressed my belief that our richest red Ceylon soils have passed (ages ago, perhaps) through the protean metamorphoses of cabook, cabook itself being the result of decomposed gneiss. Cabook soil, therefore, is no disadvantage unless it is of rocky hardness, which it certainly can be, sometimes closely simulating masses of lava. But we believe in the rapid ameliorating action of our hot, moist climate on even rocky

cabook, if only the fork, the pick or the hammer of the cultivator lays it open to disintegrating and decomposing influences. And as the hard lavas of Etna and Vesuvius, when broken up and comminuted, form the richest soil on the face of our globe, so, in degree, will broken-up cabook yield excellent soil. Of the power of the taproot of the tea plant to force itself through all opposing obstacles, Mr. Byrde saw a striking illustration. A plant growing on a specially hard piece of cabook pushed down its taproot until at length the continued existence of the substance in its rocky condition proved too much even for this most penetrating of roots, and the plant died. Mr. Byrde cut out the block through which the root had penetrated so far, and sent it to Colombo to show what the tea plant can accomplish in the way of forcing itself through hard substances. The block ought to be placed in the Colombo Museum.

(*To be continued.*)

THE WEST INDIES AND PANAMA:

NO. 7.

THE FRUIT TRADE OF PORT ANTONIO—JAMAICA—BANANA CULTIVATION—ORANGES—MANGOES—COCONUTS—PINE-APPLES AND LIMES, &C.—LOADING FRUIT IN THE MAIL-STEAMERS BY NIGHT—DEPRESSION IN THE FRUIT TRADE—THE RISE AND FALL IN THE PRICE OF BANANAS—EXTENDED CULTIVATION OF BANANAS—SUGAR FIELDS CONVERTED INTO BANANA FARMS.

Messrs. L. D. Baker & Co. of Port Antonio, an enterprizing American firm, backed up by large fruit-dealers in New York, Boston and Philadelphia, run a fleet of small craft to buy up fruit for their depot at Port Antonio, ready for shipping direct to the American market. There were many obstacles put in the way of Captain Baker when eight years ago he started in the fruit trade. The Kingston people objected to the New York mail-steamers or Atlas boats calling at Port Antonio and thereby delaying the mails. The Government, acting on the advice of the people of Kingston, thereupon stopped the steamers calling at Port Antonio (a port sixty miles from Kingston on the east coast of Jamaica). Captain Baker, nothing daunted, sailed his fleet of fruit-boats, schooner and cutter rigged, round to Kingston and claimed his space, the Government allowing him two hours to load up. The result was, by paying well by the hour, the 14,000 bunches of bananas were shipped in time and reached the American market in good order. It has since been arranged to load the Atlas steamers at night at Port Antonio, and hence the heavy work of getting the vessels off within the prescribed time.

On one occasion an Atlas steamer came into Port Antonio for bananas, but had used a portion of Captain Baker's space. He insisted on having his space already paid for, and continued to pile his bananas on the deck of the steamer in spite of the protests of the captain against overloading his ship. After a time the captain lost his patience, and ordered the bunches of bananas to be thrown overboard. "All right," said Captain Baker, "I'll have my space. Throw them overboard and let the Company pay their value; their money is as good as any other person's money," and into the sea they went over the starboard-side, as they came in on the port-side by thousands. I was informed that the late Governor of Jamaica, Sir Anthony Musgrave, was on board the Atlas boat, at the time of this banana dispute.

As the trade increased, Captain Baker, assisted by some of his relations, started the cultivation of bananas on an old sugar estate called "Bog" (formerly the property of the ill-fated Gordon executed for treason when martial law was proclaimed by Governor Eyre in 1867). Here the cane fields were cross-ploughed and harrowed, trenched up, and bananas planted, which have turned out a great success. The name of "Bog" has been exchanged for "Bound Brook," and, to insure a supply of labour to work the farm by day and load the steamers by night, when necessary, Captain Baker has built a number of cottages: about twenty-five completed, all timber, with shingle roof, painted with a mixture of red ochre, kerosine and oil; the walls are whitewashed inside and out, and locks and keys on the doors; rooms 12 by 12 and two rooms to each cottage, let to the tenants for 6s per month. Now, considering they cost from £25 to £30 to build, the six shillings per room is a very moderate rent.

Atlas town is near the seaside, so that fresh fish can be supplied at 6d per lb. daily. The banana trade is making all this change in the appearance of an abandoned district. The old ruins of mills and "great houses" are being taken down and the stone material utilized for new building foundations and abutments for bridges crossing heavy streams.

Instead of a wilderness scarcely populated, may be seen strings of ponies and mules, loaded with from 6 to 10 bunches of bananas, men and women carrying a load on their heads and backs, all wending their way to the great depot at Port Antonio.

There are other firms engaged in the fruit trade as old established as L. D. Baker & Co., but I wished to give Captain Baker credit for being one of the most enterprizing. Competition keeps the prices as high in Jamaica as can show the smallest margin of profit. Anything over eight hand bunches fetch the highest price, even up to one dollar a bunch in the season; if under six hands, they are condemned to the "Hog Pen" or rejected at the wharf if sent in for sale by small farmers. The fruit gets very much bruised on board ship: hence when sending very large bunches as a sample of 100 or 200, boxes would be made suitable for them. The same way with oranges and mangoes: the former carefully wrapped up in paper and some ventilation left in the lid of the box; mangoes are packed likewise. Both are packed green to ripen on the passage. Coconuts are brought in for sale with the husk on and sometimes with the husk removed.

There are extensive wharves at Port Antonio, and half-a-dozen steamers in the harbour at one time is a common occurrence.

Messrs. Moody & Co. do a brisk trade with Philadelphia and send their fruit-boats round the coast of Jamaica to collect fruit. Both Baker and Moody buy largely from Port Maria, Annatto Bay, Hope Bay, Buff Bay, St. Margaret's Bay, and below Port Antonio from St. Thomas in the East and Morant Bay. The banana trade is more extensive than I imagined it to be, and, if anyone in Ceylon had told me I should live to grow bananas for a living instead of coffee, I should have "smole a smile" of incredulity. We had often heard of the fruit trade of Jamaica with New York but had no idea of the extent of the trade. More than a million bunches of bananas, worth £100,000, were dispatched to America during the past year, and some, forty thousand pounds worth, about thirty-four millions of oranges with mangoes, for which there is at present not much demand.

In the height of the season, April, May and June, about half the million bunches would be shipped, for to my knowledge Baker & Co. put forty thousand bunches on board in one week! The trade must be profitable, though attended by great risks of damage to fruit in transit and sudden fall in prices. I remember seeing barrows of bananas ticketed five cents for two in New York; at that rate an eight-hand bunch would retail for about $5 or £1. One dollar is paid here, but at present the price is down to one shilling and sixpence, and the trade is rather slack.

A new steamer has been built called the "L. D. Baker," and another called the "Jessie Freeman"; these new clipper schooners can economize coal when they get fair winds, and they make a voyage in about twenty days to and from Jamaica and American ports. It must be up-hill work in the slack season to load up all the fruit fleet. Atlas Town consisted of nothing but mangrove swamp, and is now drained and built on: 20 or 30 cottages, including the barracks, and a general provision store (where no rum is allowed). Messrs. L. D. Baker & Co. are all Good Templars to a man, I believe, and Captain Baker would not allow a drunken man to work at his wharf. Yet, in spite of all precaution, the coolies and creoles would contrive to get a skinfull of old Jamaica by hook or by crook and run with a bunch of bananas on their heads and a bunch under each arm to show off their strength to the women who encouraged them with a cheer so and again. The people employed at the wharf are a happy-go-lucky lot of people, always singing and making fun of some sort.

It will be remembered that the writer came to Jamaica first from New York in the Atlas Line S. S. "Ailsa" and also voyaged in the "Arran" from Central America to Kingston. Both of the above steamers have been here to load bananas. There are some dozen steamers of this line running in the West Indian fruit trade: the "Ailsa," Captain Sansom; "Arran," Captain Brown; "Andes," "Alpes," and "Alvo," Spanish crew; "Arden," coasting round Jamaica; "Athos," "Albano," and "Aden," coasting for fruit; and others trading to Colon from Kingston. They are painted slate colour and have a scarlet ring on a white funnel, with name on the bow, and nearly all of them have houses on deck for the crew and passengers. Captain Forwood is agent in Kingston, and a nice man he is too. Employment is given to all the people who like to work on the plantations and loading vessels at the wharf, some arrangement having been made that the Atlas steamers come in at night and are not to be detained over a limited time. The plantation hands are turned out to work at any hour the Atlas boat may come into the harbour and blow her whistle. The people are paid from 4½d to 6d an hour, but often the vessels only turn up at daylight and then the people get their usual rate of pay: men 1s 6d; creole women 1s; coolies from 1s 3d to able-bodied men to 9d to women; and boys' overtime is paid liberally, and the people work fairly well. Waggons and carts drawn by mules and cattle bring in the fruit from surrounding farms or plantations, and it is valued and taken on board direct when a vessel is there, the owner of the bananas getting a receipt for eight-hand and seven-hand bunches, which is cashed immediately at the office opposite the wharf gates. There are a number of bosses tallying from carts, waggons, boats, horse and mule packs and even asses, to say nothing of numerous bunches "headed" into the wharf or depot. The scene is a busy one, good for us all, employing many people. On "Bound Brook" estate we have harvested as many as one thousand 1st class bunches in a month, so that, say 10,000 bunches per annum at $1 per bunch would be $10,000 or £2,000 with an expenditure of little over £1,000 per annum. The estate is formed of detached fields of bananas and other fruit-trees in full bearing.

BRIDGE PIECE.—Skirting the public road near the bridge leading into the town of Port Antonio, the show field of bananas, ploughed, trenched, and hoed regularly—in fact, highly cultivated.

RICE PIECE.—Near the Ranger's house (Isaac Carpenter), containing some mango trees, and also well-cultivated and ploughed.

GRASS FIELD.—Planted with Guinea grass and fenced in. Guinea grass grows well in Jamaica, and the stocks are large, and in good condition.

PLUM TREE PIECE.—Another good field of about 6 acres well-trenched and in high cultivation. Coconuts are planted on all the above "pieces."

MAN-OF-WAR PIECE, on which stands Atlas Town, is being trenched and cleaned up. The odd name given to this field was on account of the crews of the men-of-war helping themselves to fruit and sugarcane in the old time days when "Bog" was a sugar estate.

NEGRO HOUSE.—This is a fine fruit garden of itself covered throughout with coconut palms, mango trees, oranges, limes, breadfruit, &c., with bananas regularly planted and yams, eeco yams, &c., grown between the rows. The largest bunches of bananas ever seen came from the neighbourhood of the old sugar house ruins here and near the river or brook flowing through the estate and emptying itself into the sea.

BARTLEY PIECE.—Near the bungalow or manager's house, trenched and supplied with a good stock of coconut plants ready for planting out.

COW PEN RIVER.—A new clearing very promising: the bananas are growing very well, nearly six feet high in three months. A fine bathing place on the road to this field shaded by a group of mango.

GRANT'S HOLE.—A new clearing of about thirty acres being planted; now the parts finished very promising in growth. We have made two lime-kilns here, and supplied firewood to the firm regularly.

THOMPSON'S BOTTOM.—Another new clearing near Parsley's House on the highroad beyond the cattle paddock: lower part bullied by the sea crabs and land crabs; upper part of this piece is the site of the coolie barracks and planted up with bananas doing fairly well. Large plants or "suckers" were carried to this piece from Negro House field.

COCONUT PIECE.—A field of bananas near the piggery or "Hog Pen" and bounded by the river. "Hog Pen" is cleared for planting, and the pigs are to be removed to "Shotover," another property in a district called "Springfield." Bound Brook estate has the very great advantage of being bounded by the Government road at the base and by rivers east and west; the estate roads are fairly good, and carts and waggons are used on them. A bridge is being constructed by Mr. De Costa, mason, to enable the fruit waggons to go into the heart of "Negro House." (The origin of the above curious name is the fact of it having been the place where the negroes had their houses in the old time days of slavery when "Bog" was a sugar estate.) The bridge is nearly finished and is built with the stones of an old sugar house wall. These old ruins turn out very valuable in the hands of an energetic man like Captain Baker. All the foundations of the cottages and barracks are built of the same material lying idle for years and now turned to good account. My "cottage by the sea" is perfectly new and large enough for me, being a two-roomed cottage, all wood, boarded floor, shingle roof painted with a mixture of tar, kerosine and red ochre. My garden contains coconut palms, an orange tree in full bearing of good quality, and some banana plants put down by myself. The sweet potatoes, yams, bandikye, pea tree, cotton and other plants, including the tomato, are all destroyed by crabs. The mangrove swamp at the back of me harbours all sorts of vermin, rats, mongooses, mosquitoes, fleas, sandflies, crabs, and bad smells, &c., &c. There is a nursery of orange plants ready for putting out, of a good sweet orange. Baker & Co., however, do not wish to extend miscellaneous cultivation and stick to bananas.

"THE BOOK-KEEPER."—The book-keeper or assistant superintendent of an estate is to keep the people's time and go round the working place as often as possible to see that the work done is worth the money paid for it on the following Friday night. The creoles work five days, and the Indian coolies 5½ days, the pay ranging from 9d to women cooking for gangs and children to 1s and 1s 3d to coolies, and from 1s 6d to 1s 9d and 2s for coloured men of Jamaica: hoeing grass, for instance, is generally done by unskilled labour, and creole women are generally employed at one shilling daily. Felling forest, the axe-men get 1s 9d, and bosses 2s and 2s 6d. On Friday afternoon the books are made up at the office, and the "weekly pay-bill" taken in to town by the manager or "overseer," who brings out the needful bag of money. Of course there is always a little growling at the pay table, and some get sulky and stay away from work for some weeks cultivating their own yam patches and banana trees, &c. Nearly all the old people in Port Antonio own a piece of ground and house, or rent them from Messrs. Baker & Co., and other large landowners: they are rather an independent lot of people and won't stand much bullying or ill-treatment. Some of the small farmers possess good horses and ponies and ride them bare-backed, if without saddle and bridle, and a piece of rope being used for the latter. Donkeys and mules are every day employed carrrying bananas to market or rather to the shipping wharves: a mule or ass carries six bunches, and the farmer rides home on the pack as happy as a lord. Bananas falling from 3sto to 1s 6d must be a hard blow to some of them who have to pay rent for their houses to and grounds. "Breadkind" or ground provisions "keep the wolf from the door" and they work with us on "task work," trenching and felling etc., etc. Work begins at 7 o'clock.

A JAMAICA LIME-KILN.—The building of a Jamaica lime-kiln would interest your Ceylon readers, it being somewhat original. A place is selected that can be easily levelled, surrounded by heavy timber, and felling immediately commenced, the captain of the kiln allowing six men to fell and lop the trees before beginning to build. On the third morning the heaviest logs are placed round like the points of the compass, and the crevices filled in with chopped wood, the flue being in the centre about three feet square; blocks and tackles are brought to bear on the logs at a distance,

and in about ten days or a fortnight the kiln rises to a height of 8 or 10 feet from the ground, circular in shape. The women contract to break the limestone for 3d per barrel, and 200 barrels can be placed on the kiln, presenting the appearance of a huge wedding cake frosted with white sugar. When firing the kiln, men should be in attendance to regulate the fire, so as to get a uniform sample of lime and little "drunken stone," as the Jamaica man calls limestone that does not burn well. The cost of a lime-kiln of this kind is from £10 to £15, and should not exceed £20, or the lime can be purchased cheaper ready made in the town.

I have confined this No. 7 letter to agricultural subjects connected with banana cultivation in particular, and in my next will make a general report on the product of the whole island of Jamaica to enable you to put both No. 7 and No. 8 letters into your *Tropical Agriculturist.*

IS BRAZIL A FERTILE COUNTRY?

There is a very generally received opinion, in the United States and Europe, that Brazil is a wonderfully fertile region; many persons, well-informed ones too, probably regard it as the richest land in the world. There are plenty of authorities to support this idea. Scores of travellers have described its exuberance in glowing terms: cyclopædias and school-geographies have pictured the unbounded luxuriance of its forests and prairies; it is known to be the great coffee-producing country of the world, and its sugar, cotton and tobacco have long figured in commerce; the Brazilians themselves are thoroughly convinced that the agricultural resources of the empire are boundless, only needing an influx of foreign labour to develop them. In venturing a somewhat diverse opinion I shall be regarded as a heretic, unfriendly to the country and unworthy of attention. But let us look at the facts.

At present agriculture in Brazil is nearly confined to a comparatively narrow belt extending along the coast from Cape St. Roque southwards. This region is, in the main, very fertile; the decomposition of the gneiss rocks, which form most of the mountains and hills, has given rise to a rich reddish soil, generally deep and affording excellent crops of coffee, cane and other products even with the miserable no-cultivation which is in vogue. There are, however, considerable tracts of stony or badly-watered land which, collectively, are of great importance, but must practically be subtracted from the agricultural lands of the coast region.

The Amazon valley is a vast steaming forest, generally (in Pará at least) with the poorest possible soil: luxuriant as the vegetable growth is, it covers a ground composed of sharp white sand, or at best of a poor clay, almost devoid of the elements which nourish forests in other parts of the world. Most of the few plantations are on the alluvial iron-bottoms, or tracts of *terra preta* (black land), which was formed centuries ago by the rubbish and rotting palm thatches of Indian villages. Nevertheless, the Amazon village is well adapted for certain crops, and with the introduction of improved agricultural implements it will give good returns to the farmer. The forest is nourished, not from the ground, but by the air, which is always surcharged with moisture; some kinds of trees will flourish for weeks after they are cut. This excess of moisture also tends to support the growth of certain cultivated plants, especially sugar-cane, coffee and tobacco. And if the ground, even this poor clay and sand, were properly prepared to receive the roots of the plants, good crops could be obtained almost anywhere. As it is, comparatively little of the land is regarded as fit for plantations, and these are generally abandoned after a few years.

All the great interior region, comprehending the Brazilian table-land, is covered with *campo*, interrupted here and there by little patches of forest on hillsides and along the banks of streams. Botanists who have travelled through the *sertão* have been struck with the immense variety of families and species to be found among the *campo* plants, and they have naturally fallen into the error of regarding it as remarkably adapted for plant growth. The truth is that nearly all of the Brazilian table-land is a howling sandy desert with a wonderfully rich desert vegetation. The botanist may find a thousand species of plants on a square league of land; but I doubt if the same land would produce a thousand bushels of corn or of potatoes. Much of the country is adapted for pasturage, but only in the wet season; during the dry months cattle must be driven away to the lowlands. The little strips of forest-land can be used for planting and in some places they give good crops; but they form only a small part of the whole. A large district comprising parts of Ceará, Piauhy, Rio Grande do Norte, Pernambuco and Bahia, are subject to periodical droughts, which destroy the cattle and plantations and reduce the entire population to the utmost poverty—often to starvation.

Two elements which go far to determine the fertility of Europe and the United States are almost or quite wanting in Brazil: the winters and the action of earth-worms. Our northern winters are of immense assistance in the formation of vegetable mould. The herbs, grass and forest leaves die away in the autumn and lie in thick beds on the ground, where they are speedily covered with snow; successions of thaws, and finally the spring rains, reduce these leaves to sudden masses; as the sun returns they decay slowly, forming a rich, dark soil, replete with the elements of new plant-growth. In the tropics, the leaves and herbs fall singly, are baked in the sun, broken by the wind, and finally pass away almost entirely in the form of gases, hardly anything being added to the soil. Add to this fact the influence of frosts in breaking up and disintegrating rocks, and the importance of winter cold in the formation of soils will readily be seen.

The elaborate studies of Mr. Darwin have shown that the despised earth-worms are the preservers of our farms and gardens; unseen workers, they are ever bringing up the rich sub-soil and strewing it over the surface: boring the ground in all directions, they keep it loose and soft, and fit it for the roots of even tender plants. Now, earth-worms are by no means common in Brazil: they are altogether wanting in the *campos* and even in the forest they are rarely seen except along the banks of streams. Probably the sandy soils so prevalent in Brazil are ill-adapted to them; very likely, too, they would be of less use in ground which, by its nature, is friable and easily pierced by roots. At all events they are an element, of greater or less importance, which is nearly wanting in Brazil.

I have written all this in no harsh spirit; rather as a friend of Brazil. I wish to point out a mistake which might, in the future, lead to grave troubles. The first element of success in the individual, or in a new country, is a thorough knowledge of the resources, or weak points which must determine success or failure. Brazil has great resources; it has elements of agricultural wealth which are far from unimportant; but by overrating its own riches it may be tempted to waste them; by resting too securely on agricultural industries it may neglect the no less important ends of manufactures, mining, grazing and commerce. Brazil is far too large and important a country to be content with one element of success She should seek for all. HERBERT H. SMITH.

Rio de Janeiro, Feb. 19th, 1885.—*Rio News.*

AGRICULTURAL RESOURCES OF INDIA.

Sir James Caird, F.R.S., presided on Jan. 23rd at a meeting of the Indian Section of the Society of Arts, when a Paper was read by Mr. E. O. Buck, Secretary in the Revenue and Agricultural Department of the Indian Government, on "The Agricultural Resources of India."

In the course of his address Mr. Buck said he was one of those who was convinced that under British rule the position of the agricultural population and the producing capacity of the country were, and would continue to be, materially improved, and he was not afraid to assert that the resources of India were capable of a further development, which it was impossible as yet to measure. The great want under which Indian agriculture laboured might be described in one word, "rain." Although the monsoons of India conferred upon it its agricultural rank amongst other countries, yet within India itself they varied immensely and created enormous varieties of climate in combination with two other varying factors—the temperature due to latitude and the dryness due to distance from the seaboard. The consequence was that there was no crop in the world which India could not produce. Notwithstanding the fact that while monsoons conferred agricultural wealth the uncertain character of the rain in the greater part of the country was so excessive that the agricultural out-turn, so far as it depended on the rain of the year, was subject to violent oscillations. How to overcome the oscillation, or to mitigate its effects was the great problem which had to be solved, and it was he (Mr. Buck) was glad to say being vigorously attacked and to some extent solved in India. The system of agriculture was eminently one of *petite culture*, and it was no exaggeration to say that the country was split up into many millions of five-acre farms, the holders of which were small tenants paying rent over a large part of India direct to the State and over a still larger part to a landlord, or a landlord intermediate between them and the State. The State as landlord-in-chief was now engaged in the promotion of railways, canal, and well irrigation, the improvement of the revenue and rent systems, the reclamation of waste lands, the establishment of fuel and fodder reserves, the introduction of agricultural improvements, and finally emigration. A great deal had been done to assist agriculture in India generally, but there was yet much to be accomplished, but of this people might rest assured, that whatever pictures might be drawn of local distress in some parts of India, in the greater part of the Empire the condition of the cultivators was materially better than it was fifty years ago.

In the discussion which followed, Mr. Seton-Karr, Mr. Wilson, Mr. Reed (a Bengal planter), Sir Hugh Lowe (who, from his experience of Perak, advocated free immigration from India to the Malay States), and Mr. Pedder, were among the speakers.

Sir James Caird, in conveying the thanks of the meeting to Mr. Buck, complimented him on the clear and graphic picture of India, both physically and in relation to its people, which he had placed before them. It was a good augury of its success that the head of the new Department of Revenue and Agriculture had a firm and clear hold of his subject, and well knew how to handle it in practice, and it must give great confidence to those who had placed him in that responsible and onerous position to know that he would treat the subject with knowledge and with care. It must have been most agreeable to those who had any experience of India to find that a termination was about to be put to a system by which the really impossible attempt was made to fix a valuation upon soils, since, however experienced the officer might be, it was impossible that he should be able to tell that one soil or another was worth one rupee more or less than that beside it. It was to be hoped that the Government, while dealing in a just and liberal spirit with the sub-landlord, would take care that the latter should be bound to act in a like spirit with his sub-tenant, the actual cultivator. Mr. Buck stated his belief that the agricultural resources of India were capable of great development, and the need of this was sufficiently obvious, since in every ten years provision must be found from it for an additional twenty millions of people. The magnitude of the country and its resources, fifty times the population and fifty times the extent of the cultivated land of Egypt, as he had pictured it, was in one grand point inferior to Egypt and in another superior. It was not like Egypt watered by a fertilizing Nile, which periodically renewed the productive power of the soil. But, on the other hand, the actual debt of India, independent of the capital invested in remunerative works, was little more than one year's revenue, while Egypt was burdened with a crushing debt of fourteen times its revenue. . . The Government of India, Sir James observed in continuation of his remarks, now proposed to adopt measures to promote the full working power of the great human machine by extending railways, by canal and well irrigation, by improvement of the revenue and rent systems, by the reclamation of waste lands, the guardianship of common pastures, and finally by assisting migration and emigration. With regard to irrigation, he agreed with Mr. Pedder that where wells could be got with water at a moderate depth from the surface, say 30 ft., and where they could profitably be used, there was no system of irrigation in India so perfect as that by which each little cultivator could command a supply of water on his farm, and apply it wherever he required it. In speaking of canal irrigation he thought Mr. Buck had not alluded to the great distinction between the northern and southern irrigation. The northern irrigation was the water taken from the melting snows of the Himalayas. Reverting to other topics brought forward by Mr. Buck, Sir James Caird said, in conclusion, that in the judicious promotion of each of these would be found the truest safe-guard for the continued progress and welfare of India and its best protection in time of famine. To the other members of the Famine Commission, as to himself, it was specially comforting to find that each one of these objects, after careful consideration by the Commission, had been pressed on the attention of the Government of India with a convincing clearness and force for which they were indebted to the ability of their secretary, Mr. Elliot, now Chief Commissioner of Assam. And to Lord Ripon, by his acceptance of them, belonged the honour of grasping the true position of the country, and of having laid during his Viceroyalty the foundation of principles which it faithfully carried out must largely contribute to its future prosperity. (Cheers.)—*Home News.*

FISH-CURING IN THE MADRAS PRESIDENCY.

We have received from the Madras Government the report of Mr. Bliss, Commissioner of Salt and Akbári Revenue, on the fish-curing operations during the half-year ending 30th September 1884, from which we learn that there were 124 yards open at that date, as compared with 106 on 30th September 1883; 69,125 applications, against 24,353; 143,312 maunds of fish brought to be cured, against 72,086 maunds; 23,707 maunds of salt issued, against 13,002 maunds; R13,830 worth of salt sold, against R7,901; the quanity of salt issued to each maund weight of fish being 13·61 lb., against 14·84 lb.; while the expenditure incurred by Government was R9,181,

against R6,028. It will be noticed that the only decrease was in the amount of salt issued for each maund of fish: this is a favourable sign in some cases, for, as Mr. Bliss remarks, in writing of the Chicacole division,

Less salt seems almost everywhere to be used as the curers get to understand its use better.

This is not the case everywhere, however, for we read regarding the Namlipātam division:—

The proportion of salt issued to fish cured at the Coringa yard was very low. The cause of this is being inquired into.

And again of the Nellore divison:—

The proportion of salt issued to fish cured is very low, and varies greatly in the several yards. This is explained to be partly due to the ignorance and poverty of the curers and partly to the size of the fish cured. Probably, however, as the curers gain experience, the proportion will adjust itself to a tolerably uniform standard. Our own experiments, which are being conducted with some success in this division, will also tend to produce this result.

Respecting the Tinnevelly division we read:—

All the old yards, except Adirampatnam, also show satisfactory progress. The falling off at Adirampatnam is reported to be due to the fact that the curers are not fishermen by profession, but only traders who advance sums of money to, and obtain their supplies of fish from, the fishermen at Point Calimere, where the takes of fish were small owing to the prevalence of adverse southerly winds during the months of June and July. This cause also accounts for the operations at Point Calimere not being as large as they might otherwise have been. The opening of the Muthupettai yard has also doubtless affected the operations at Adirampatnam.

The place referred to is a sea-town south of Pt. Calimere. Under the Tinnevelly division, it is stated that

The Ramesvaram and Periathorai group, which is also worked alternately, shows a marked decline, the quantities of fish cured and of salt issued being less than half of those in the corresponding period of last year. The cause of this great decline will be inquired into.

The following general remarks are of interest:—

The number of yards at the beginning of the half-year was 135; eight new yards have since been opened, and nine old ones were permanently or temporarily closed, leaving 134 yards at the end of the half-year. Of these, 27 were not used. The majority of the unused yards (17) were in the South Canara District. The causes of their failure have been explained above. Of the remaining yards, two were opened only towards the close of the half-year; the abolition of six is under consideration; one is to be transferred to a better site; and one is reported to have done no work owing to the season being unfavorable. The total weight of fish brought to be cured in the half-year was 143,312 maunds or 5,264 tons. In the corresponding half of the previous year, there were 106 yards, of which only 60 were worked, and 72,086 maunds or 2,648 tons of fish were brought to be cured. There was, therefore, an increase of 2,616 tons or of nearly 99 per cent., in the supply of food rendered available. The quantity of salt issued averaged 13·61 lb. to each maund of fish cured, as against 14·84 lb. in the corresponding half of the previous year. Explanations have invariably been called for in all cases in which a striking variation has been observed. It will be seen that the low proportion is almost always confined to new yards. Where it occurs in old ones, it is due partly to the size of the fish cured and partly to the state of the weather. No very large experiments were made with improved methods of curing in the half-year under report, but such as were made proved fairly successful. At two yards in the Calicut Cricle, 262 maunds of fish were dealt with, and the price realized in both cases was 8 annas a maund in excess of that realized for fish cured in the ordinary manner. The price would, no doubt, have been higher had the fish experimented upon been of the finer kinds, instead of shark and cat-fish. Special instructions had been issued not to spend money on inferior sorts of fish, such as shark, but the difficulty of procuring the finer varieties at the time led to these kinds being used. Another experiment conducted by Mr. Inspector Beeson at Kistnapatam, in the Nellore District, was more successful. The fish cured in the course of this experiment were sent by Mr. Beeson to Madras, and realized a profit of about 33 per cent., which was very satisfactory. I have ordered the experiment to be repeated on a larger scale. The fish cured in the improved manner is reported to be eagerly bought, and a trader in Madras has offered to purchase any quantity that may be available. No doubt, the curers will in time find out that it will pay them to take more trouble, where a market can be found for a better article, that is, in the neighbourhood of large towns. The lower classes appear indisposed at present to pay more for fish cured in a superior, and therefore more expensive manner.

On the financial results Mr. Bliss says:—

The expenditure incurred at the yards during the half-year amounted to R9,181. Adding to this the cost of the new office establishments above referred to the expenditure amounted to R9,901 or R2,886 more than in the corresponding half of the previous year. Calculating the financial result of the half-year on the principle indicated in paragraph 10 of my report for the half-year ending 31st March 1884 (G. O., No. 1,025, dated 11th September 1884, Revenue Department), the operations resulted in a loss to Government of R2,564-13-6. The total expenditure on fish-curing from the beginning has been R97,121-11-11 excluding, and R1,02,003-2-0 including, interest. The total receipts have been R77,323-7-7, so that the loss to date is R19,798-4-4 or R24,679-10-5, according as interest is excluded or included. It is very disappointing to me that the half-year under report should end with a loss, and that a somewhat heavy one. I can only say that, if operations continue to expand during the current half-year, which is far the best for fishing, in anything like the same ratio as in the past, the result of the whole year should be more favorable. If the expenditure on the yards which have proved failures, or which have only just been opened, is deducted, the loss during the half-year was only R1,819, which will not, I hope, be thought serious, considering the importance of the subject and the magnitude of present operations.

In submitting this report to the Government, the Board of Revenue remarked:—

Mr. Bliss shows that the work has resulted in a slight financial loss, but the Board hope that when the unsuitable yards are eliminated and the expense of starting new experimental yards is no longer incurred, the fish-curing operations will be financially profitable.

The Government Order dated Feb. 21st, 1885, says:—

The Government concur in the markets of the Boards of Revenue in paragraph 3 of their proceedings, and they desire that the result of the inquiries instituted as regards the low proportion of salt issued to fish cured at the Coringa yard and the decline of operations at the Ramesvaram and Periathorai gronp be reported for their information.

BENGAL NOW AND NINETY-ONE YEARS AGO.

The history of the little book* which lies before us is curiously illustrative of the way in which works of considerable value may be entirely lost sight of even when the authors are men of recognized ability. The treatise was written in 1794, as part of a volume which was intended to contain also accounts by other gentlemen of the manufactures and external commerce of Bengal. Though printed in 1794 it was not published, as the book was considered objectionable "on account of the dangerous free trade principles which it supported with powerful arguments." When in 1804 Colebrooke published his own part of the treatise both in Calcutta and London the authorities of Leadenhall Street, as Max Müller tells us, considered him a "dangerous young man" and there is

* *Remarks on the Husbandry and Internal Commerce of Bengal.*—By Henry Thomas Colebrooke, late of the Bengal Civil Service. Calcutta, printed 1804. Reprinted, 'Statesman' Steam Printing Works, 1884.

some ground for supposing that his advanced opinions stood in the way of his promotion. The essay has long been out of print, and copies seem to be very scarce so that it was only after a long search that Mr. R. Knight was able to obtain one for the purpose of making the present reprint.

The change in the value of produce and of labour is shown best in the following table given by Mr. Knight in a note which he prefixes to the reprint :—

	1793.	1884.
Population	25,000,000	60,000,000
Acres under tillage ..	31,000,000	70,000,000
Gross rental on Ryots...	4 crores	13 crores
Grain per maund ...	As. 8 to 12	R. 2 to 3
Ghee per seer ...	As. 3	As. 12 to 13
Cattle per head ...	R. 4 to 5	R. 20 to 30
Agricultural Monthly Wages	As 8	R. 2
Urban do	R. 1	R. 6 to 7
Value of exports ...	£2,000,000	£30,000,000
Value of money ...	100	33
Gross value of harvests	32 crores	250 crores
Proportion rents to harvests	1 eighth	1 twenty-fifth

If we accept these figures we cannot help being struck by the enormous change in the value of labour and produce during the last ninety years, and we see how great a loss the Permanent Settlement was to the revenues of the country.

Leaving the debateable ground of rent we turn with interest to what Mr. Colebrooke relates of the commerce of Bengal in 1794. Internal commerce was much hampered by the want of roads, for at that time there were no roads in Bengal suitable for carts, and all goods had to be carried on bullocks, or horses, to places that lay at a distance from the great rivers. Still the cost of carriage was not excessive, for he calculates that by water the freight did not exceed R4 on a hundred maunds for a hundred miles, while by land it might be taken on an average of R1 a maund for hundred miles. The export of sugar to England had just begun before the pamphlet was written but the trade was greatly hampered by the excessive charges for freight and duty, East Indian sugar being charged an *ad valorem* duty at the rate of £37-16-3 per cent while West Indian sugar had to Pay only 15s. a ton. The cost of the best sugar in Calcutta was then about 6 sicca rupees for the factory maund (of which 30 went to the ton) and a calculation made by Colebrooke shows that at the price the sugar then obtained in the London market a profit of £8,423, could be made on a consignment of 500 tons, reckoning freight at £6 per ton, and duty at the West Indian rate. But the freight of £15 per ton charged in the Company's ships, and the high duty charged with the object of protecting the East Indies, really changed this possible profit into a loss of £1,523. Similarly in the case of cotton ; the best cotton could be bought in the Calcutta market at £2-15 per cwt., and with freight at £15 per ton could be landed in London at 12¼d. per pound, and with freight at £6 per ton at 9¼d. per pound. At the time of writing the cultivation of indigo had just been revived, and was beginning to become of commercial importance. The average price was about 120 sicca rupees per maund which however left only a small margin of profit to the cultivator. Saltpetre was even then manufactured to the extent of 200,000 maunds per annum, and cost the Company about R67 per ton, while at the same time the cost of manufacture in Spain was not less than £88-10 per ton, but the trade was greatly hampered by restrictions placed on its export. Turning next to articles which had only been exported on a small scale Colebrooke points out how important the trade in hides might become, and all know how fully his expectations in this respect have been realized. His estimate of the possible profits on this trade in 1791 is as follows :—

100 buffalo hides at R. 2½	R. 250	0			
225 bullock do „ 1½	„ 337	8			
	587	8	or £58	15	0
Freight at £6 per ton			12	0	0
Insurance and uncovered risk at 10 per cent			7	1	6
Charges, duties &c., at 15 p. ct. on 77 16 6.			10	13	6
			£88	10	0
Sale of 100 hides at 10s ...	50	0	0		
225 do. — 5s ...	56	5	0		
	£106	5	0		
Leaving a profit of £17	15	0			

Other less important commodities did not escape Colebrooke's attention, and we find him pointing out the value of such articles as gums, annotto, madder, coffee, cocoa and cochineal, and he writes "no argument occurs against the probability of . . . even tea thriving in British India." He saw at the same time that the only way of developing the resources of India was by the introduction of free trade, and the removal of the many restrictions which rendered private enterprize impossible at the time at which he wrote.—*Madras Mail.*

A WOMAN TO WOMEN ON COFFEE AND TEA.

I have previously referred to coffee in my article on tea, and propose to say a few words thereon. Not coffee-tea—though that exists as the great beverage in Sumatra and the islands of the Eastern Archipelago, tea being made from the roasted coffee leaves, of a very nourishing and supporting quality. It is, however, of coffee as we know it and use it that I would speak. Very few people in England, unless they are connoisseurs in the matter, care what kind of coffee they drink, but they may speedily detect the real kinds when they see them unroasted ; for instance the Arabian, or Mocha, coffee is small and of a dark yellow colour ; the Javan, or East Indian, a blueish, or greyish green tint. Now there is a very curious fact about coffee, which is that it distinctly improves with keeping. The Arabian takes three years to ripen, and even the worst American coffees in ten or fifteen years become nearly as good as the best Oriental ones. There is a great deal in the way coffee is roasted ; and to drink it in perfection, of course, it should be made immediately after roasting and grinding. It is also best to buy it in the bean and grind it yourself, as the ready-ground coffee admits of more adulteration.

Many people like an admixture of chicory in it. First used as an adulteration, the use of chicory became so general that the sale of it was legalized. It adds a bitter taste and a dark colour to coffee, and is supposed to be an economy in the use of the latter ; but it is a doubtful good to those who can afford to buy pure coffee, as chicory is as much adulterated as coffee itself. I quote from Prof. Johnson, an authority in these matters :—"Pure chicory is as difficult to be met with in the market as unadulterated coffee. The common ground chicory of Berlin contains half its weight of wasted turnips. On the Rhine the carrot is used along with other roots instead of the turnip. Venetian red is also very commonly employed to impart to the chicory a true coffee colour ; and it is curious to observe how the practice of adulteration extends itself from trade to trade. The coffee-dealer adulterates his coffee with chicory to increase his profits ; the chicory maker adulterates his chicory with Venetian red to please the eye of the coffee dealer ; and, lastly, the Venetian red manufacturer grinds up his colour with brickdust, that by his greater cheapness, and the variety of shades he offers, he may secure the patronage of the traders in chicory."

Of course the most highly flavoured is Mocha, but this may be advantageously mixed with East Indian. If a less expensive coffee for daily use is required, a combination of East Indian and Plantation I find very good at 1s. 3d. a pound. English people somehow seldom succeed in making coffee properly. The best coffee-pot is the ordinary French *cafetière*, that divides in two parts, with a large-holed drainer at the top and a finer one half way down, and a little flat stamper. Warm your pot thoroughly, then taking out your top drainer, put in the coffee which should be fresh ground, but not too finely, and stamp it hard and flat, allowing two teaspoonsful to each person; replace the drainer. Then remember that your kettle must be *boiling over* before you attempt to pour water into the *cafetière*; this should be done slowly at first, and unless you hear it running through too fast at the bottom, continue pouring until coffee and water rise together through the holes of the top drainer, then stop, and set the *cafetière* close to the fire on a trivet, or somewhere to keep it very hot, without stewing it. First fill your breakfast-cups half full of boiling milk, then pour a little of the coffee, which will be very strong, into each cup, it will be sufficiently strong to add some water in each case. Then replace the *cafetière* by the fire, pouring more boiling water into it, so as to keep up a good supply for second cups. By this means you will, I think, be able to emulate the best coffee ever made abroad.—*Weekly Echo.*

PLANTING IN FIJI:

A GREAT VARIETY OF PRODUCTS: YARAWA ESTATE, SERUA.

This plantation, belonging to Messrs. Baillie Bros., is situated midway between the wet and dry districts on the south coast of Na Viti Levu. The estate is 400 acres in extent and, on the plan, presents a very queer appearance indeed, the proprietors, when purchasing, secured the right to select their area in whatever shape they chose, out of a block of 1,600 acres; so they took the hearts of two rich valleys, connected by a narrow strip over a saddle and running up only to a certain elevation, so that the surrounding unpurchased, and thickly timbered heights give the requisite shelter from strong winds. Additional cover is provided by breakwinds of native forest left at effective points about the plantation. The *desiderata* aimed at—moderate rainfall, rich friable soil on volcanic rock, ample protection from gales, and ease of transit—have certainly been attained, and the vigor and productiveness of the cultivated plants (of widely different tropical and sub-tropical families) prove the wisdom of the selection. The part under cultivation is the valley nearer the sea, where about 90 acres of carefully tended Arabian coffee * are now in prolific bearing, most of the plants are absolutely loaded with crop and present, with their grey, radiating branches, the glistening green of the crimp-edged leaves, the white flowers and profusion of berries—in every stage from dull green to bright yellow and brilliant red cherry—a very picture of beautifully contrasted tints. The whole plantation is intersected with contour roads of slight gradient, in addition to the main leading to the dwelling-house, and these exhibit many interesting varieties of economic vegetable growth, and color in foliage. Cinchona,* with their clear stems of dull purple, and umbrageous tops of light green, corrugated leaves with tinted midribs. Ceara Rubber,* the bright brown bark crisping off and oozing caoutchouc, and their tri-branches, tri-branchlets and indigo shaded tri-leaves, forming even a better emblem of the Trinity than the shamrock of blessed memory. Cocoa with old leaves green and young ones brownish fawn; the green bark of the Cinnamon and their scented, yellow green, oval leaves, quaintly marked with a lesser oval as are those of the indigenous Mathou (*Cinnamomum s. p.*); the tall, grey stems of the Teak, straight, branchless, and crowned with a few leaves, rough and huge; Tea * with their upward sweeping green branches, delicately serrated leaves, and nut-like seeds; Liberian Giant Coffee * looking sturdy and defiant, their large leaves of blackish green shining as tho' glazed; Jack trees, whose produce (of delicious flavor and awful stench) grows out of unexpected places on the stem and looks like Brobdignagian bread-fruit; the dull, dark leaves of the Soursops * whose crop is as of cotton-wool soaked in nicely acidulated custard; the Sweetsops, and their light green leaves with a wonderful sheen of old gold; Custard-apples * and their too sweet fruit looking something like a cross between small breadfruit and young pine-tree cones; Mangoes with their brown stems and slender leaves (the upper ones brown fawn) and the fruit like—well, like a hot-house peach blended with a ripe and superior Fijian *wi* (*spondias dulcis*), and grown in Paradise; the light green stems of the Areca (betel nut); Palms,* their large feather-like leaves and brush blossoms of most delicate straw color; Tobacco * with its long leaves mottling yellow as they ripen; indigenous and imported oranges, lemons, limes, shaddocks, pineapples * and bananas.* At the house grandilla * and grape vine * guavas * and mulberries * are all bearing profusely; and tamarinds, with their acacia-like leaves, are growing; while, the purely ornamental is there represented by many varieties of the brilliant-hued croton, coleus dracœna, caladium, etc. Of Cinchona there are about 6,000 plants of different kinds in various stages of growth (3½ years to 1 month) and there are blocks of these valuable medicinal plants in addition to those growing along the roads. About five acres of bananas in bearing, with plenty of tubers, (yams and white kumalas) ripe and ripening, keep the main food supply up to concert pitch. Nearly all vegetables seem to do well here, the cabbages have the solid white hearts which memory associates with colder climates, and in the salad line one can really feast *ad lib.* on water-cress and tomatoes. The plantation valley has several nice little rocky creeks, in one of which is a deep hole for the refreshing and necessary daily dive. When splashing about under the fall one certainly swallows sometimes an undue proportion of pure water, but it doesn't seem at all injurious when promptly modified. Close to the bathing-hole and fall is the two-storied coffee store and factory (of wood and iron) containing the necessary fittings and appliances for pulping, drying, hulling, (*i. e.* husking or peeling) etc. It is so placed that water power could, if required, be readily and inexpensively applied to the machinery. The labor houses are scattered about on points of vantage, near to, but well above, the main creek, and a very fat, healthy, happy lot the laborers seem to be. The surrounding hills and adjacent valleys are clad in forest, whence one may glean many a rare lycopod, lichen, fern and fungus, with here and there an orchis or an orchid. Hard and soft and ornamental timbers abound; and the indigenous nutmeg, with its gaping, mace-wrapped seeds, is frequently met with, as are, of course, the ordinary Fijian fruits. Now I dont know what more there is to tell you about this pretty place, except that it is well worth seeing and I wish I owned (not to break—the tenth commandment is n't it?) just such another, in just such a position. It has plainly cost much skill, work and money, and looks to my judgment more like good returns than any other I have seen in the group. I append a statement of the rainfall for 1881-4, for which I am indebted to the Messrs. Baillies.

CEYLON PLANTING: SEEING THE TEA GROW: WITH A GLANCE AT CACAO, CARDAMOMS AND OTHER "NEW PRODUCTS."

(*Continued from page 856.*)

LAVA LIKE CAAOOK AND GNEISS—SULPHUR IN CEYLON—ORIGIN OF OUR HOT SPRINGS —ARE THERE ANY VOLCANIC TRACES IN CEYLON?—CAUSES OF OUR ROCK FORMATION —NO EVIDENCE OF GLACIAL ACTION IN CEYLON—RICH SOIL FROM THE DISINTEGRATION OF ROCKS—TERRAICNG HILL SIDES—RESULTS OF FORKING—TEA ESTATES IN THE KELANI VALLEY—GRAND FOREST TREES—CHENA AND BAMBOO LAND—LUXURIANT NILU A SIGN OF GOOD SOIL —UNGROUNDED FEARS—A TRYING ASCENT WELL RE-PAID—TEA AND CARDAMOMS ON AVISAWELLA ESTATE —FOREST TREES—EXCESSIVE FOREST RESERVE TO BE DEPRECATED—SUPERSESSION OF WOOD BY IRON.— CARDAMOMS IN AWISAWELLA,MADULKELE AND MATALE —MALABAR AND MYSORE CARDAMOMS—ENORMOUS PROFITS FROM CARDAMOMS ON KANDANUWARA— PREPARATION OF CARDAMOMS—CACAO CURING—BLACK-MAN'S AIR PROPELLER—SILKWORMS—CULTIVATION OF CACAO—RED ANTS AS A CURE FOR HELOPELTIS— SUPPLIES NECESSARY IN DRY LOCALITIES—CACAO ON HILLY AND ON FLAT LAND—BEAUTY OF CACAO ESTATES —ENEMIES OF CACAO—RUBBERS—LIBERIAN COFFEE A FAILURE—CROTON OIL PLANTS—COTTON TREES— TEA—CHANGES IN NAMES.

I have alluded to lava-like cabook, and pieces can be picked up with exactly the molten-like surface of true lava of rather recent origin. But the power of much-weathered gneiss to imitate old lava rocks is still more striking. I saw many instances in my journeyings, but perhaps none more curious than a series of black crags scattered over a portion of Dunedin tea estate with holes of all shapes and sizes worn through their substance. They reminded me of loose lava rocks, through a tunnel in which the trains from Messina in Sicily to Catania at the foot of Mount Etna have to proceed with extreme slowness for fear of shaking down the roof of the tunnel. Had I been in a volcanic country, I should certainly have ranked the grotesque, dark gneiss masses on Dunedin and some other places as volcanic, but neither of sulphur nor of soda was there a trace. Indeed, I do not know of sulphur anywhere in Ceylon except in the pyrites of the crystalline limestone of our mountains. Even the hot springs, which are pretty common in Ceylon, probably owe their warmth to masses of decomposing vegetable matter. Sir Emerson Tennent talks of basalt in Ceylon, and, therefore, I should be very sorry to be dogmatic. All I can say is, that I have walked over the lavas of Vesuvius and those at the foot of Etna, not to speak of Java and Aden, and I have seen the basalts of Australia and Western India, but trace of true volcanic rock in Ceylon I have never yet seen. Gentlemen so intelligent as Mr. T. C. Owen and Mr. M. H. Thomas assured me, however, that what they regarded as a true volcanic formation existed on Oonoonagalla or on the route thence to Galheria Unfortunately I was not able to visit the spot, but I am promised specimens, on receipt of which I may be able to judge. What I did see on Oonoonagalla, passing in from Hatale and again on the opposite side of the rock over Dotaloya, was the truly stupendous effect of atmospheric influences on gneiss abounding in felspar and hornblende. Enormous masses of rock lay scattered about, not rounded boulders, but detached fragments of the strata of the parent mountain. A look in this case and others of like nature was sufficient to show that the rock ruins around were due to no great cataclysm, but to the operation of causes still and constantly at work, pale hued faces of the mountain above, showing where huge laminæ had been quite recently detached. It is curious that so observant a writer as Sir Emerson Tennent should have propounded the theory that the same agency which originally upheaved our mountain system can be looked to as accounting for the *débris* of rock fragments which lie scattered from summit to base of many of our hills. Some of our lower hills may possibly, owe their origin to this cause, but I think all the evidence is in favour of the whole mass having been upheaved intact, and to an altitude probably a full third greater than that of our highest mountain, Pidurutalagala, which is 8,296 feet above sea-level. Twice that height would carry our mountains up to the snow-line even in this latitude, but as far as I know there is as little evidence of glacial action as of volcanic in Ceylon. What seems certain is that against the outside of our mountain system the sea waves once beat, while lakes of collected rain water in situations like Nuwara Eliya at length burst the barriers which confined them, engineering their way into the lowcountry through what are now river beds; while we owe the disintegration of our mountain peaks and their conversion into rounded knolls of rich forest-bearing soil to the agencies of tropical heat and monsoon moisture still at work, acting on the chemical constituents of the rocks. Magnificent and picturesque as some of our mountain cliffs are—for instance, the circlet of rocks running from Hantane to Galaha, the spotted rock ("Kabaragala") above Nawalapitiya, Etapola and ridges over "the Knuckles,"—yet the distinguishing characteristics of our mountain system are succeeding series of smooth, rounded knolls covered either with forest or the cultivation which has displaced "the forest primeval." It is no new thing to say that the richest soil has been found and the most teeming crops produced amidst scattered and confused rock and boulders, beneath cliffs, as in the case of Oonoonagalla, where we were not surprized to hear that a ton an acre per annum had been frequently gathered amidst the labyrinth of rocks through which we had difficulty in winding our way. Besides the rich soil accruing from the decomposition of the rocks, there were the conditions of shelter, warmth and moisture afforded by the huge masses. The splendid coffee-bushes amongst the rocks still exist and still give promise of crop, and will be the last, we may rely on it, to give place even to tea such as we saw on another portion of Oonoonagalla, and which, in thickness of stem, vigour of growth and luxuriance of golden flush, compared favourably with anything we had ever seen, even in the Darjiling terai. In Dimbula there is excellent soil with scarcely a sign of detached rock or boulder, the latter having been doubtless weathered and decomposed.

In the northern ranges rock fragments of all sizes are the common accompaniments of the finest soil, and when we heard that proprietors of tea estates on low hills in the neighbourhood of Awisawella were horrified and disappointed at finding the surface of their land strewed with broken stones, our remark was that the disappointed ones could not have visited or heard about some of the very richest because rockiest estates of Haputale and Rangala. To compare the rocks of the Awisawella estates to those of the Haputale and Matale ranges, would be to compare great things with small, but the small things can be gradually most beneficially utilized in forming terraces to preserve the surface soil. Terracing for this purpose is a very different thing to cutting terraces on hill-sides which would

bring the stiff, inert or sour subsoil to the top. An experiment on the estate whence I write is most interesting and promising. Stones, where they exist, are used to protect the upper sides of paths. Then small drains a few inches deep are cut at distances of a couple yards apart, following the contour of the ground, and into these are placed and covered over with soil all pruniogs, fallen leaves, weeds and fragments of decomposing timber. With forking carried out in the spaces between the terraces thus formed, cultivation is perfect, the weeds decomposing and yielding manure. We were told that encouraging results had not followed forking on one of the Awisawella estates, and we should certainly think the best results from that process cannot be attained until the rock fragments on the surface of the soil have been arranged into terraces round the hill faces. We believe the expense of the operation will be more than amply repaid, forking and ultimately manuring being then possible. The tea estates in the Lower Kelani Valley have been opened on all descriptions of land. In forest so grand that Mr. Byrde told me of a hora tree he had measured when felled, the length of which was 189 feet, the girth and cubic contents being in proportion. To utilize forest like this, steam saw-mills were used, but the enterprize, we believe, proved unprofitable in competition with superior advantages enjoyed by "lumberers" in the valley of the Kaluganga. Transit in the latter case is probably easier and cheaper. Then places, like Penrith, are being opened on old chena equal to forest, while a couple of estates we visited en route to Mipitikande had been formed from bamboo-land, the bamboo being not the great borer-breeding *Bambusa arundinacea* of the Wynaad and Coorg, but the small Ceylon *batali*, the undergrowth of many of our jungles. On enquiring with some surprize, we were told that the profuse existence of the small bamboo was really a sign of good soil, and certainly the growth of tea bushes on Spring Vale was all that could be desired. In Upper Dimbula or Lindula here, our forest generally is very poor compared with the tall giants of the Lower Kelani Valley and especially the tremendous trunks and umbrageous heads of the Matale trees,—trees which contractors hesitate or refuse to face. Of course altitude and climate account for much, but when, in prospecting we suspected poor soil, we were reassured by the statement that a luxuriant undergrowth of NILU (*strobilanthus*) always indicated a rich soil, and certainly, as it has turned out, a finer and more suitable soil for tea there could not possibly be found, such being the decision of a succession of Assam authorities. Now that the earth has been cultivated under cinchonas or tea, or each in succession, for some eight years, its appearance, when terraced as described above, surprizes ourselves as well as others. We mention the matter as an encouragement to some who may have needless fears as to poor soil, like the purchasers of property near Awisawella, who were frightened at the carpeting of broken stone they found on this soil. Those stones, built into terraces: conserving soil, warmth and moisture and themselves gradually decomposing, may yet prove the chief elements in the successful culture of tea in that region. Reversing Shakspere's epitaph, let us say:

"Blessed be he who moves those stones,"

into terraces encircling the hills like necklaces. The stoniness of the soil as well as the fierce heat of the atmosphere rendered our ascent through the fine tea (some of it "Indigenous Assam") on Avisawella estate somewhat trying, but oh! the delightful change and instant relief when we attained the summit at 700 feet or so above sea-level and commenced a walk through forty acres (they seemed four hundred) of Malabar cardamoms. The plants themselves, with leafy branches rising from twelve to twenty feet high, were sufficient to afford a large proportion of shade; but the cardamom plantation was effectually shaded and so were we by a grove of the noblest possible trees, common to Ceylon, some of them valuable timber trees. Happily the proportion of valuable timber trees in the forests of the hill regions of Ceylon, destroyed in the process of clearing, is small. The case is different in the forests of the lowcountry, and adjoining Avisawella we saw land, the property of one of the numerous clan Fernando, the timber from which had over and over again repaid the price paid for the land. Cases of this kind, as well as the advisability of setting aside forest reserves for timber, have doubtless influenced Government in its present obstructive policy as to the sale of lands suitable for tea. But, the climatic argument put aside as absurd, in a monsoon-engirdled island like Ceylon, Mr. Vincent's own report yields the best reasons against excessive forest reserves. The number of timbers which the public will purchase and use is, after all, exceedingly limited and the localities whence even such timbers can be cheaply conveyed to market are also very few. Besides which the tendency of our day is everywhere to supersede wood by iron in structures. Take only the case of old iron rails. They have been largely used in the erection of coal sheds and in bridging streams, and they will be more and more used in the construction of factories and withering houses on tea estates, combining as they do strength with the quality of occupying but a fraction of the space taken up by stone pillars and thick wooden posts. The use of iron, too, will decrease the real danger from fire. Let us hope, therefore, that a moderate and wise policy in regard to forest reserves may prevail such as will not check the enterprize on which the reviving prosperity of the colony depends. Much of the now forested lands in the valley through which the noble Kelani flows in its course of nearly one hundred miles from mountain to sea can be spared for clearance without climatic, scenic, or economic injury resulting.

We were amongst the luxuriant cardamoms and the noble forest shade, on the top of Avisawella estate, when we concluded our last instalment of notes of our journeys up the Valley of the Kelaniganga. More luxuriant cardamom growth we did not again see on our journey, the *débris* even of fallen stalks being enormous. Mr. Byrde considered the use of the knife in removing withered stalks inadmissible, as the stalks died back and so far weakened the stool. Withered branches here were, therefore, pulled up, but subsequently on other places we found cutting resorted to. The mode in which the acemes of the "Malabar" cardamoms creep along the surface of the soil was not in accordance with our sense of the fitness of things, and here and elsewhere we suggested wooden shingles or flat earthen tiles to be placed beneath the fruit stalks. We were told, however, that neither rain nor soft earth splashed up did any material damage, although we certainly preferred the upright habit of the fruit-stalks on the Mysore cardamoms which we subsequently saw growing on the top of Goomera estate. In both cases the plants flourished, the Mysore kind being much more independent of shade. Thrse, however, as far as our recollection goes, we saw nowhere except on Goomera. In proceeding from Oonoonagalla, under the guidance of Mr. M. H. Thomas, we passed through either a mile or two miles of fine cardamoms,—fine generally, although exceptional spots showed that this plant above most others desiderates rich loam. Shady and well watered ravines are evidently its favourite haunts, and in a ravine of this description we saw some most promising plants belonging to Madulkelly

estate and to Mr. Owen's new clearing below it. But the cardamom fields which most impressed us, from their enormous yield of fruit and the profits stated to have been already derived from them, were situated in a dense grove of magnificent timber trees in the lower part of Kandanuwara estate. In this case the effects of the long continued drought had been more than counteracted by the utilizing of a fine irrigating stream, the effects of which, added to the deep rich soil, were wonderful.

Coffee, before the fatal fungus appeared, gave grand returns on Kandanuwara, but the berry in its palmiest days never gave profits at all approaching those derived from the spice here and in some other cases. Unfortunately the demand for cardamoms is limited, the market is getting glutted, and prices are going down. If the worst comes to the worst, however, the cardamom plants can be uprooted in favour of tea, which will flourish none the worse for the previous cultivation. On Kandanuwara we not only saw the richest yielding field of cardamoms (although a good many bushes had been smashed down by the fall of giant trees, victims to a limited but violent cyclone in December last) but witnessed and had explained to us the whole process of preparing the seeds, from the gathering to the sulphuring which bleached them white. But it was only those gathered before being quite ripe which turned out white. The seeds left to ripen fully were distinguished by a colour resembling that of Indian corn, while the large white seeds gave one the idea of very well prepared parchment coffee. We saw and received a specimen of a box of large, choice cardamoms which are, we believe, to be exhibited at the Kandy Show. Other cardamom-growers will have to be on their mettle to beat the No. 1 Kandanuwara spice. Besides the Malabar and Mysore cardamoms, there is a plant indigenous to Ceylon, the elongated seeds of which, however, are deemed inferior to the foreign kinds. I need scarcely say that I gave a wide berth to the sulphuring-house at Kandanuwara store, although as a Scotchman, I am, of course, no more inclined to undervalue the good properties of sulphur than to refrain from bestowing a blessing on the Duke of Argyll. Equally unattractive as a place of human sojourn, was Mr. Robert Fraser's weird-looking hermetically closed (when the door was shut) chamber for "sweating" the cacao beans, of which his magnificent trees yield so many. Readers of the *Observer* are aware that from cardamoms a liqueur is prepared, and a similar use is made of the matter which oozes from the cacao beans in the process of curing. But the most scientific process of cacao curing is to be seen as carried on by Mr. A. Ross on Kawudapelella, where a Blackman's air-propeller (so favourably mentioned, and we believe with good reason, by Col. Mouey, as enabling tea manufactories to regulate the temperature of their withering-houses,) is worked by a steam engine. On this machine, which is not costly and which is most effectual in both the propelling of fresh air through a building and attracting hot or foul air from it, we shall have something further to say. We had proof of its power of rapidly removing hot and vitiated air from a loft where, besides millions of silkworms' eggs, tens of thousands of the worms themselves were feeding on mulberry leaves, with a crunching noise, as if of cattle chewing; others weaving beautiful cocoons of white and golden yellow silk filatures. The experiment is most interesting and we should say likely to be successful. Mr. Ross's fear was, in view of the fearful voracity of the insects, that his supply of mulberry leaves would give out, although immense and luxuriant hedges of the plant lined the roads through these magnificent grounds. We should hope that the leaves of some of the numerous forest trees, so plentiful around, might be found suitable. In any case, the mulberry culture can be rapidly extended. The eggs were brought by Mr. R. S. Fraser from China or Japan, with much else peculiar to those countries, while from Trinidad Mr. Fraser has introduced not only the best kinds of cacao but the beautiful *immortelle* which the South Americans regard as the mother of *Theobroma*. Mr. Fraser has also reproduced in his truly magnificent cacao groves at Wariapolla, names so well-known in Trinidad as those of the valleys of "San Antonio" and "San Francisco," while some of the trees he brought thence show what the cacao can attain to as it increases in years, the years of its life being not threescore and ten, but, if properly cared for by successive cultivators, a couple of centuries. We have said "cultivators," but really the amount of cultivation required by this beautiful bush, which vies in its vari-coloured foliage with the vivid spring tints of the Ceylon mountain forests, is of the smallest, once it is settled in the soil. As it covers the ground it eradicates weeds, and the amount of pruning and handling demanded is almost *nil*, although we felt inclined in some cases to advise stripping some of the umbrageous foliage to admit "more light" to the splendid pods, some of which, we were told, gave twice the twenty-five seeds usually regarded as the average. We were amused to learn that Mr. Vollar, on his well-roaded cacao fields, believes in cherishing the large red ant as an antidote (pun unintended) to *Helopeltis*. Of the latter, I saw neither specimen nor effect in my rounds, the bared points of branches visible in some cases being attributable, so planters insisted, not to the insect but to drought. Mr. Robert Fraser considers the couple of men he employs to go round examining the trees and disposing of pests when discovered a sufficient assurance against the insect which, in some less favoured localities, has proved so destructive. One of the men carried a chatty of tar, to be applied, we understood, should sign of canker appear on any of the stems. But of any such affection we saw no sign. As a large portion of the cacao which has succeeded in Ceylon is situated in regions liable to drought, we were scarcely surprised to learn, that, unless careful precautions are taken, repeated plantings, or, if not, a large amount of "supplies," will be necessary, the plants ,according to Mr. Ross's experience being most difficult to establish on flat ground. On the lower sides of steep hills, where the soil is rich, they specially flourish. Such is the description of the locality in which grow Mr. Drummond's celebrated seed-bearers on "Gaug Warily" in Dolosbage. The top of the estate is about 3,000 feet above sea-level, we believe, but it is down in the hot climate and rich soil of the sides of ravines, at an elevation of only eighteen hundred feet that the cacaos specially flourish. So in Kawudapelella, but we are bound to say that in Dumbara and on Wariapolla, near Matale, nothing could be finer or more luxuriant than cacao growing on comparatively flat land—with undulations sufficient to secure good drainage. The great requisite conditions seem to be rich soil, almost perfect shelter, and, at low elevations at any rate, a certain amount of shade. A tea estate, brilliant with its green and golden expanse of foliage, spreading over hills and valleys, is certainly pretty and pleasing, but for scenic effect there is no comparison with groves of large warm-foliaged cacaos, overtopped and shaded by noble forest trees. Of course, the gathering and curing of the first involves anxious labour and care, but the cultivation of well-established cacao bushes requires so little work, neither pruning nor handling being necessary, that we expressed our fears to our ever-active friend, Mr. Ross, that some day he would be found, native fashion, sitting on his hunkers and waiting for the falling of

the pods. He groaned in spirit and replied that any such consummation was too good to be true. Animal enemies of the cacao plant, not to speak of insect plagues, are sufficient to keep planters on the alert. Mr. Drummond has recorded his troubles with the omnivorous *Paradoxurus*, one of which cut the jugulars of nine *Observer* carrier pigeons in one night, using papaw fruit as a corrective. While going round under some of the romantic precipices of Kawudapelella with Mr. Ross, we came upon a troop of little rilawa monkeys *in flagrante delicto*, who scolded violently at being disturbed at their afternoon cacao and Mr. Dewar showed me on Roseneath a boulder on which a porcupine had mounted during the night, broken down a pod-laden branch, and feasted on the contents, leaving the fragments behind him. So secretive in habit are these latter creatures that an offer of R5 per caput had been but poorly successful, and as for ourselves, although we have resided many years in Ceylon and moved about a good deal, we have never seen a porcupine in the wild state. The case is different as regards wild hogs which in the lowcountry have almost eradicated rubber trees (those allied to the cassava), grubbing them up for the sake of the tubers. Mr. Robert Fraser still retains his faith in these trees, of which he has a large well-grown grove on Wariapolla. He desiderates more mature age for the plants, but that is just the difficulty with most planters: they cannot wait any lengthened period for returns. On Mipitiakande, besides luxuriant tea, pruned so that the bushes met I saw some nice cacao plants and also some really fine Liberian coffee trees, scenting the air with their large white blossoms. But, with most planters, faith in this once-promising product is lost even more than in regard to indiarubber trees. The cherries do not properly ripen, the pulp is tough, and the proportion of waste matter is outrageous, while in England there is a prejudice against the bean. We suppose that in regard to no single new product were hopes so sanguine or disappointment so entire and bitter as in the case of the big-leaved, big-blossomed, large-fruited West African coffee. I can speak for myself at any rate. I am taking such crop as there is from trees, many of which look really fine, to make room for tea. This is on a lowcountry estate near Henaratgoda.—One of the very prettiest subsidiary cultures on estates is the croton oil plant, and, as the oil from the seeds is used not only in medicine but for dressing cloth, there is hope of profit from this clove-like plant, which Mr. Holloway has used as shade for cacao. I saw some fine cotton trees, by the sides of the road from Badulla to Spring Valley estate, but Mr. Ross's magnificent lines and avenues, closely planted of this tree, excel anything I have previously seen. A good deal of the fine short wool (the "kapok" of Java) has been gathered and profitably sold, both in the rough and cleaned state. If the trees are only kept clear of the parasite *loranthus* which so affects them, they will long continue a valuable property, and, should thinning out be required, the timber is good for tea boxes. Pieces of the tree stuck into the ground for fences grow readily.—Having thus dealt with subsidiary products, I hope in my next instalment of notes to return to tea in the Kelani Valley, following it into Dolosbage, the Nawalapitiya Valley and Gampola, in the neighbourhood of Kandy and on the ranges running northwards to Matale and beyond into the comparatively arid regions at and below Dambool or Dambulla, the second syllable of which the late Mr. Campbell of Islay was of opinion should be written, Scotch fashion, "het." The writer of "Circular Notes" would not have joined the Calcutta press in calling for the intervention of the Bishop, when the vowel *a* was substituted for *u*, in the name of the great military station, near Calcutta, known, before the reformed orthography was insisted on, as Dum Dum. The new name reminds us of the sad fate of a Kelani Valley estate which began life with the grand appellation of Ruwanwella, the golden field or plain. But as coolies and letters intended for the estate went miles away to the station of Ruwanwella, the name was changed to *Dewalakanda*. The awkwardness of such a name becomes obvious when we remember that the Sinhalese *w* is generally convertible into *v*. "Spell it with a wee, my lord," is all very well, but so good a man as Sir Charles Peter Layard, when troubled in the Colombo Kachcheri about a series of Dewal lands, was so far left to himself as to exclaim, "What the Dewal is it all about?"

FIBRE CULTIVATION AND PREPARATION IN SOUTHERN INDIA AND CEYLON.

We attract attention to the interesting and valuable letters on this subject which will be found on pages 868-9. To Mr. J. W. Minchin of the Glenrock Company, Limited, Wynaad, our especial thanks are due for one of the most sensible, moderately stated and thoroughly practical expositions of the experiences and difficulties connected with the utilization and cultivation of fibrous plants that we have yet seen. Our thanks are also due to Mr. Le Mesurier of the Ceylon Civil Service for placing at the disposal of the public the information supplied to him in connection with the cultivation of New Zealand Flax. We trust this example will be followed by other public servants in charge of revenue districts, or who may have friends in other colonies, in reference to the development of the resources of Ceylon, the introduction of new agricultural industries or the utilization of raw products now going to waste. Our Civil Servants need to be reminded that the Minute against writing to the public press—which not a few are so fond of referring to as a shield for their laziness or want of public spirit—rather encourages than prevents communications on subjects of general public interest, merely forbidding the discussion by public servants of controverted political topics or the indulgence in criticism of the Government whom they serve.

As respects Fibres, it will be seen how clearly practical experience both in Southern India and New Zealand, and we may add in Ceylon, controverts the popular notion that there are many fibre-yielding plants growing wild and running to waste, which could be so utilized by machinery as to yield large profits. Again and again has this idea been exploded by experience only to be taken up again by some one new to the subject. But Mr. Minchin and Mr. Halcombe show that the quantity available of such raw material is far less than is usually anticipated, even under the most favourable conditions while the cost of carriage, alone under the circumstances of collecting from wild plants, is well-nigh prohibitory. It may, in fact, be assumed as an axiom that cultivation alone can bring any fibre-yielding plant within the bounds of profitable experiment. Mr. Minchin makes another very candid but most reasonable admission that in respect of the cheaper fibres, it is very doubtful if Europeans even with machinery, can compete with native processes. This has surely been pretty well demonstrated in Ceylon in the case of Coir fibre, where the native industry and native processes have held their own notwithstanding many improvements in machinery.

Mr. Minchin affords statistical results of great value to any who may be contemplating experiments in the utilization of fibrous plants; and very striking is the difference in the proportions of raw stuff to

marketable fibre as given for plantains and rhea and by Mr. Halcombe for New Zealand flax. The latter talks of 3 tons of raw product giving nearly 1 ton of fibre, or say a proportion of 30 per cent; while Mr. Minchin got only 1 ton of fibre each from 100 tons of plantain stems, and from 34 tons of rhea stems, or 1 and 3 per cent respectively. The difference here in favour of the *Phormium tenax* is very great; but we suspect this plant makes too heavy a demand on the soil to suit the Ceylon cultivator, save in exceptionally favourable positions. No doubt, the alluvial soil on the banks of the Mahaweliganga in the Eastern Province would grow it to perfection, but, after the experience of tobacco-growing in that neighbourhood, we fear there is not much chance, just yet, of European capital being introduced for fibre cultivation thereabouts. The day, however, will come when the resources of Ceylon will be more fully turned to account in respect of fibres. As Dundee "jute" men have repeatedly said after visiting the neighbourhood of Galle and Colombo, the island should be "the paradise of fibre-yielding plants." Mr. Minchin's figures seem to show that there is a sufficient margin for profit when the raw material can be collected with reasonable facility. This has been the experience of Europeans in Ceylon in connection with coir: given the coconut husks free of cost and the fibre can be profitably prepared. It remains to be seen what will be the result of the Glenrock experiment in the cultivation of 250 acres of rhea. We shall watch it with the deepest interest. Meantime, we would mention for Mr. Minchin's information that the result of prolonged experiments by Mr. Charles Shand of Colombo went to show that the best results were got from the stems of the *Yucca gloriosa* which yielded 12½ per cent of fibre and which grows fairly well in very poor sandy soil.

A few months ago we dealt at some length with the question of cultivating Rhea in Ceylon, and called on Dundee capitalists to take a practical interest in the subject. Soon afterwards we heard from a gentleman of influence in the "Fibre" mercantile world in London that he had taken up our suggestion and was hopeful of being able to float a Company, largely supported by Dundee men, to experiment in the direction referred to. We have not heard for some time what progress has been made, but as we know that some of the supporters of our friend, are interested in the work undertaken by the Glenrock Company, it is possible that a halt has been called, so far as Ceylon is concerned, until the result is known of the cultivation of 250 acres with Rhea in the Wynaad. If that be so, it will serve to increase our interest in Mr. Minchin's future communications.

Planting in the Sulu Archipelago.—The next day I visited Captain Schucke's estate which lies about two miles out from the town. The land is generally flat, and between the fruit trees, some of which are of immense size and afford an agreeable shade, cocoa and Liberian coffee are planted in carefully planted rows. The oldest cocoa is five years old and was fruiting freely, and the vigorous appearance of the trees gives promise of a remunerative future. The soil is particularly rich and well able to withstand a long drought. Captain Schucke has opened about 80 acres. I was particularly interested in an antidote to canker, or grub, or beetle, which he explained to me. It appears that the cocoa in the Philippines has been for some time affected with a disease which kills off the trees at short notice, and from which, Captain Schucke about a year ago found his plantation suffering. He tried several remedies but without avail. One day a convict (the Government are sometimes willing to lend convict labour at $4 a month) drew his attention to a sickly tree, and digging round the root, produced a couple of white grub, and further explained that a beetle laid its eggs in the bark. Their presence in the bark causes it to turn to a reddish-brown like the canker in the cinchona in Ceylon. Having cleaned the tree of these parasites and cut away all the infected bark, it was necessary to apply the antidote, which consists of ginger root. A bit of the root is squeezed into the cankered places and also into the bark of the tree, as follows:—A small wedge of ginger is cut and a downward puncture made in the bark of the tree. The knife is held in the wound which is opened by a slight pressure and the wedge of ginger is pushed in tight. This should be done say in three places, and the effect on the tree will be seen in a few days,—*British North Borneo Herald*, April 1st.

New Test for Tea.—It has been asserted that the quality of tea may be approximately estimated by the weight of ash which it yields, the value of tea being inversely proportional to the ash. M. Nikatinski has lately, says the *Grocer*, made a series of experiments with the view of testing the truth of this assertion, and finds that the ash is a very fair index of the quality of the tea. Thus a good Shanghai tea gave 5·16 per cent. ash, a cheap green brick tea 6·87 and two Orenburk teas, which are known to be adulterated with rose leaves, and of which the price was 115s. and 48s per cwt., yielded respectively 7·87 and 10·42 per cent of ash.—*European Mail.*

Sugar Planters all the world over are in a very unfortunate position. Of 1,100 planters in Louisiana, United States, it is computed that at most 50 are able to exist, or, rather, to vegetate, without advances from the commission merchant; the other 1,050, however, obtain advances under the most oppressive conditions, and in the most humiliating fashion, and must then pay 25 to 45 per cent interest. Nominally the rate is less, but only nominally! They pay 8 per cent actual interest, and 2½ per cent commission; 2½ per cent for buying, 2½ per cent. for selling. Then come brokerage, insurance, cooperage, insurance, weighing charges, and whatever else each lengthy charges account includes. The contracts which must be entered into to obtain advances, and in which a mortgage is given on the whole plantation, with everything upon it movable and stationary, dead and alive, are usually so formed that the planter loses all control not only over the sugar but over the growing crops as well.

Gum from the Blue Gum Tree.—The *Indian Agriculturist* states:—Our readers have become pretty familiar with the tree known as the *eucalyptus globulus*, an indigenous tree of Australia, the product of which has been so largely utilized in the arts and manufactures. We now hear that a process has been invented in America for the manufacture of a preparation of the gum of the *eucalyptus globulus*, which promises to be of invaluable help to shipowners and others interested in the shipping interest. It has the effect of removing thoroughly the scales which form in engine boilers, and prevent rust and pitting. A Company has been formed and a factory erected at Piedmont, with a capacity of 1,000 gallons a day and employing 30 men. The result of the introduction of this preparation has been so great, as to create an immense demand for it both in America and Europe to an extent of which the Company could hardly form an idea when it started the concern. The effect of this preparation in preventing the pitting and corrosion of boilers will, it is expected, extend the period of their usefulness 100 to 150 per cent., and at the same time effect a great saving in fuel, as scale is a non-conductor of heat, and therefore more fuel is required to generate steam in old boilers than in clean new ones. This may, if all that is claimed be true, tend to decrease the manufacture of boilers, but, on the other hand, it will lessen the liability of explosions. The Company have also embarked in the distillation of the essential oils of the *eucalyptus globulus*, which are extensively used for medical purposes, and which have heretofore been supplied in Australia, it being found that the oils can be produced at a profit. With this object in view, the Company propose to set out extensive forests of *eucalyptus* trees, in order to have at its command a sufficient supply of leave, the portion of the tree consumed in the manufacture of the oils,

Correspondence.

To the Editor of the "Ceylon Observer."

THE FIBRE ENTERPRIZE IN SOUTHERN INDIA:

PRACTICAL RESULTS WITH DEATH & ELLWOOD'S MACHINES ON DIFFERENT FIBRES: CULTIVATION OF RHEA ON A GREAT SCALE.

The Glenrock Company, Limited, Pandalur, S.E. Wynaad, 5th April 1885.

DEAR SIR,—As requested I give you such information as I am as yet able to afford as to fibre cultivation and the working of Death & Ellwood's machines. The Glenrock Company erected eight of Death & Ellwood's Machines here drawn by a turbine last monsoon. It was proposed, while land was being brought under cultivation with rhea, aloes and other fibrous plants, that an effort should be made to utilize the indigenous fibres of the district. Trials have accordingly been made with the *Conocephalus niveus*, a jungle plant of the nettle tribe, *Urena*, a kind of wild jute, and the wild plantain which is found on the forest slopes.

We soon learnt that the quantity of indigenous fibre available within easy reach was not enough for any regular work, and the cost of collection and carriage from any distance was prohibitive, considering the quality of the fibre obtained from wild plants of different size and growth, evenness in length and staple being an important element in value.

The conocephalus grows into a small tree, and it was impossible to utilize and clean the bark from the larger stems. By pollarding, and layering under the soil the larger stems, good clumps of young shoots have been obtained, and fibre from these has been favourably reported on, but the quantity as yet grown is but small. The urena fibre growing in small patches here and there in the lighter sholas could not be collected at a price to pay, considering its small value as jute, say £12 to £15 per ton.

Wild plantain has been successfully treated, and in course of time a large enough quantity may be obtainable. A small parcel has been sent to England for report. A small trial has also been made with the Manila hemp plantain. These trials have enabled us to form some idea of the capabilities of the machines, and the cost of cleaning and preparing the fibre for market, as well as the percentage of fibre that can be got from the green stems.

The following are actual statistics of outturn and cost of a parcel of Manila hemp plantains. The cost of treatment of material, giving 1½ per cent of marketable fibre to the ton of green stems treated, is at the rate of £5 per ton of fibre produced.

Outturn of Manila Hemp Plantain from Mr. Guard.

January 28th, 1885.—Stems, 179; weight, 10,973; machines worked, 6; time occupied, 5 hours 25 minutes. Good fibre, 140¼; discoloured, 4½; waste or beating, 14¾: total 159½ lb. Result 1·49 per cent marketable fibre, say 1 machine in 32½ hours, 337 lb. green stuff per hour, 4-9 lb. fibre per hour. Labour (8 men machine, 1 boy carrying, 6 women drying and sorting, 2 men beating &c.) cost R4-3-0 or R63-8-0 per ton of fibre for treatment in machine and preparation drying.

(Signed) C. J. LARGE.
(Initialed) J. W. M.

Reduction Works, 31st Jan. 1885.

It may be urged that 3 cwt. of green stuff or five pounds weight of fibre per machine per hour is a small quantity, but the bulk of the material passed through must be considered, and the question is rather one of cost than the output from one machine. Three shifts of men working day and night will treble the daily output of the machine, and the number of machines must be increased according to the delivery of raw material. Each machine requires 1 lb. of the motor to work it.

The following calculations of the cost of treatment, according to the percentage of fibre to the ton of green stems, have been made from actual working. With coarser fibre, such as plantain and aloes, the machine can be fed with larger quantities at a time. With rhea and more delicate fibre greater care is necessary.

Cost of treating Plantain and Rhea Fibre in Death & Ellwood's machines—allowing one hundred tons of green plantain stems to produce one ton of fibre, and thirty-four tons of rhea green stems per ton of fibre, taking two tons of green plantain stems and one ton of green rhea stems per machine for 8 hours' work.

100 *Tons of Plantain Stems.*

At machines 100 men at 5 annas ...	R31	4	0
Currying and beating 50 men at 5 annas	15	10	0

(Signed) C. J. LARGE.
(Initialed) J. W. M.

The great cost of fibre treatment lies in the carriage of the raw material to the mills, seeing that from 30 to 100 fold the amount of ultimate produce has to be handled.

The percentage of fibre in the material treated, and the comparative value of the same, and facility in delivering the green stuff at the mill, are the main points to be considered.

It is very doubtful whether Europeans with machinery can compete with the native retting process, on the cheaper varieties of fibre.

The Glenrock Company have decided on the cultivation of the rhea nettle as the fibre which commands the best price.

It is not generally supposed possible to obtain stems for treatment in the first year after planting rhea.

It has been our object to propagate plants for a considerable acreage, and so far we have been most successful in this, and hope to have enough plants for nearly 250 acres of land this monsoon, which will be about twelve months from the commencement of operations. Arrangements were made to obtain stock plants from Algiers, the Kangra Valley, Saharanpore, Calcutta and Bangalore, and extensive seed nurseries have also been laid down.

From plants put out during the monsoon of 1884 we hope to be able to obtain a cutting of stems fit for treatment during the current months of April and May, although until lately all the shoots and stems have been used for propagation, as cuttings and layers. About four strong succulent stems are now growing from all the established roots: these are now about four feet long, and will be from five to six feet, by the time they have hardened ready for cutting, the growth being at the rate of about one inch per day.

It appears necessary to irrigate during the hot months. Some portion of the planting was left without water for the purpose of comparison, and since the beginning

of February there has been no growth of stems on the plants not watered, while on the adjoining plants that have been irrigated the stems are four feet long. The unwatered plants, though not growing, are alive and strong, and appear to have made root freely, although not so strongly as those watered. There is also very great difference in the growth of plants in the hollows and on the ridges, showing their appreciation of good soil and moisture, and the plants in the open have apparently done better than those under shade. Three of the original roots, which have not been cut up for propagation, and which were planted in a nursery in February 1884, have now over 20 stems each, which will shortly be fit for cutting. It is not until the third year after planting that the normal crop can be expected. Two hundred and fifty acres of forest land have been prepared for planting with rhea here.

The largest trees have been left standing for shade, at distances of about 50 feet. The site selected is on the slopes of a valley surrounding the mill-house, the top of the range being about 600 feet above the mill. Three streams of water are available for irrigation, and three main channels carrying the water round the hill-sides have been made at about 200 feet in elevation apart. The jungle is lopped, heaped and burnt, so as to save the standing shade trees from fire. The soil is then thoroughly dug over to a depth of twelve inches and all roots run over. It is then laid out in beds, on the slope of the hill, with intervening water channels, at distances of 6 and 12 feet, according ing to the lay of the land. In China and in Algeria the plants are put down at a distance of 18 inches from each other, which on level land without drains or obstacles would give 16,000 plants to the acre ; but it is generally found necessary to remove the alternate plants in the second or third year. As tillage is very necessary, and on 18 inches there is no room for even a pick to turn the soil, while, from our present short experience, the ground is covered at 18 inches apart in one year, we have decided on planting the rows three feet apart, and the plants 18 inches apart in the rows ; this, with allowance for drains, trees and stumps, gives about 7,000 plants to the acre.

As the produce is of a very bulky nature, a cart-road has been made to tap the main fields, and numerous foot-paths to facilitate work. It is also proposed to lay wire ropes from the principal ridges to the mill to shoot down the raw stems.

For exogenous fibre plants like rhea the decortication process by steam of Monsieur Favier is most useful. Steam generators or boilers have been made, to weigh when empty about 6 cwt., which can be wheeled along estate roads and the stems carried to them and skinned in the field, saving the carriage of the weighty stems to the mill.

This process as well as the machines of Messrs. Death & Ellwood, will be thoroughly tried, so that the comparative cost and value of the results by the two processes can be tested. The steaming process has been tried on the young shoots of the conocephalus satisfactorily, but not on a sufficient scale to judge of the cost.

But we are satisfied as to the successful growth of the rhea, and that it can be treated by either the Death & Ellwood machines or by M. Favier's steaming process, and in the course of another twelve months commercial results will be obtained.

The Glenrock Company are also erecting mills for the treatment of the indigenous moorva fibre in the Bhowani Valley under the auspices of Mr. H. P. Hodgson and Mr. C. A. Paterson, and are laying down fields of rhea and fourcroya.

The water channel some 3½ miles long to bring water for the turbine there is a big business, but extensive operations will shortly be carried on there.—Yours faithfully, J. W. MINCHIN.

NEW ZEALAND FLAX—IS CEYLON SUITED FOR ITS CULTIVATION?

Matara, 15th April 1885.

DEAR SIR,—I send you some papers connected with the cultivation of the *Phormium tenax* for any use you may care to put them to.

It appears to me that the rich alluvial land along the banks of the Mahaweliganga near Trincomalee would be admirably suited to the cultivation of this flax. I thought at one time that the swamps in the Matara district could be utilized for the new product, but Mr. Halcombe's replies to my queries have quite knocked this idea on the head.—Yours faithfully,

C. J. R. LE MESURIER.

Lichfield, Auckland, New Zealand, 12th Feb. 1885.

C. J. R. Le Mesurier, Esq., Ceylon.

My dear Sir,—Mrs. Halcombe has given me your letter of the 12th Oct. 1884 to reply to, and as I happened to be a member of a Commission appointed by our New Zealand Government to enquire and report on the industries connected with the Phormium Tenax, I am supposed, though possibly erroneously, to know something about it.

As perhaps you are aware, some years ago New Zealand was a little mad upon the subject, everyone who had a few acres of flax (Phormium tenax) if he was wise sold it at a very high rate, but if he were a lunatic, as most of us were, bought machinery and expected to make a fortune, and very many thousands of pounds were spent in starting flax-mills all of which came to utter grief. There were two grand reasons for the failure. 1st, that the self-grown supply had been in every case enormously over-rated, and 2nd, that it could not stand the high rate of wages which obtain in New Zealand.

With cultivation and with cheap labor I believe it would pay. But before putting money into it I would very strongly advise you to find out all about the cultivation of the Manila hemp (also a species of aloe, I believe) as its fibre commands a better price in the market, and I am under the impression that it is more easily cleaned.

You know, I presume, the appearance of the Phormium Tenax plant and the general character of its growth; if you do not, I shall probably have a difficulty in making myself understood.

I and my fellow-Commissioners came to the conclusion that only under cultivation was the Phormium Tenax likely to become a staple article of commerce. Growing wild as it does so freely in New Zealand, the person collecting the raw material has many disadvantages to contend against; the plants are spread on perhaps 20 times the area which the same number of plants really require for their growth, and a lot of rubbish of various kinds has to be cleared away by the collector. Then the facilities of getting at the Phormium Tenax when bundled were in most cases anything but good. Then, and worst of all, the system of cutting was always reckless in the extreme, only the outer leaves of each palmated frond were mature, but the whole frond was cut off including two sets of leaves both immature and both useless, which should have been left for future supply, and their cutting bled the plant to death.

As fully three tons of green leaf are required to produce one ton of fibre, the importance of reducing the cost of collection and carriage of raw material is, you will see, very great. This expense, in fact, with our high price of labor, and the bad quantity of it into the bargain, killed the industry, and the only mills which are at work now, and they are doing well, are some small ones which get their raw material cut by Maories and carried by water to the mill, and where the proprietor of the mill does all the work without hired labor.

I feel aware that the climate of Ceylon is admirably adapted for P. T., and when I was at Point de Galle a few years ago, I saw plenty of patches of ground where it would have grown to perfection. It is a mistake to suppose that the P. T. likes swamps. It grows in swamps certainly, but it does best on really well-drained, rich, light, alluvial soil which gets an occasional overflow of water, but it will do very well without the overflow if the

land is fairly moist. The kind of flax grown by the Maories in old days for their fine mats, fish-lines, &c., is that called "Tihore," and they always planted it on ground such as I describe.

Mrs. Halcombe some months ago sent you a bag of flax (P. T.) seed through General Fielding. It would be enough to try the experiment of cultivation with this at first. I believe, that it would do well with you, but you will, I expect, have to use machinery for working it, unless the Sinhalese are like our Maories of old days, utterly careless of the value of time.

The information I am able to give you as to the results or the cost of cultivation is very scant, for no one does cultivate it methodically. The plant when cultivated will last very many years, so the cost of planting would be debited to a great many years cutting, and the produce of green leaf per acre from land properly cultivated and properly cut plants I have no means of estimating, but I am quite sure that I am within the mark in saying that you would get three tons of mature leaves the third year which would give a ton of clean fibre.

A. FOLLETT HALCOMBE.

P.S.—I see by the Government return that last year 2,013 tons of Phormium Tenax valued at £36,667 were exported from New Zealand. So the process of cleaning must pay where the supply of the raw material is plentiful.

QUESTIONS.

1. Does the cultivation of Phormium Tenax *by itself* pay anywhere? and if so, what are generally the essentials to its profitable cultivation?
2. What would be considered a fair average return per acre over an extent of, say, 50 acres exclusive of cost of opening?
3. What should be the ordinary cost of labor per head per diem under such circumstances?
4. What soil does it flourish in best?
5. Will it grow profitably under a tropical sun 110° to (?) 120° Fahr. and in a temperature of from 80° to 90° Fahr. in the shade?
6. Will it grow profitably on land that is under water part of the year and parched up with drought at another?
7. Will it grow profitably in swamps or in land that is almost, if not entirely, under water all the year round? And if so
8. How should it be planted in such land?
9. How is an ordinary clearing of it planted up?
10. Is it propagated from seed (or bulbs) or plants, and if the former, should the seed be planted in a nursery or at stake or broadcast, and if planted from the nursery, at what distance apart should the plants be put out?
11. Do the young plants ever require shade?
12. Does the clearing require weeding?
13. Where can seed be obtained and at what cost?
14. How much seed does it take to plant an acre?
15. Does it require any particular care after it is once planted out until it comes to maturity?
16. Does it require manuring?
17. How long does it take from time of sowing to first crop?
18. How many times a year can a plant be cropped?
19. How and when is it cropped?
20. How many days' labor of one man does an acre require a year for upkeep?
21. How is the flax prepared for the market? *ab initio* and in detail, please. 1st by hand, and if machinery is used 2nd by machinery. N. B.—As an enterprize for the natives machinery would be out of the question here, at the beginning.
22. Where is the best market first? and what is the present market value?
23. Is the market a limited one or would demand increase with supply?

REPLIES

to Questions re "Phormium Tenax," its Cultivation, &c., by Mr. Le Mesurier.

1. In New Zealand the P. T. has never been cultivated except in very small quantities by the natives and as a garden plant by Europeans.
2. We have no experience in New Zealand sufficient to give a reply to this.
3. The cost of labour in New Zealand is from 4s to 6s per diem.
4. The P. T. does best on a rich, well-drained, alluvial soil which is subject to occasional inundation, such as low-lying flats by the sides of rivers.
5. It will, I think, grow profitably under a hotter sun than New Zealand. In the northern extreme of New Zealand it flourishes well under a summer heat quite as great as suggested.
6. I do not think the P. T. would flourish under a very long drought, but in such a soil as that suggested in para 4th it would stand several months drought when once fairly established.
7. The P. T. will grow in swamps, but the fibre from the swamp flax is not as valuable as an article of commerce, and the cost of collection would be greatly increased by the difficulty of working in mud and water.
8. It should not be planted at all in such land.
9. The plants should be four feet apart, in rows five feet apart. With an extra space about every tenth row sufficient for a native cart to move for collection of the leaves.
10. The P. T. is propagated by seed, which should be planted in a nursery, and planted out at a twelvemonth old, as detailed in para 9th.
11. The young plants are very hardy and would not require shade unless transplanted in very dry hot weather which would not be advisable.
12. The plantation would require to be kept clean until the Phormium Tenax plants has taken full possession of the ground which would be in the third year from the sowing of the seed, if the ground were rich.
13. The best way to get seed would be to apply to the New Zealand Government through your Government; Dr. Hector who is curator of the Government Gardens in Wellington and an enthusiast on all such matters would get it for you; the cost would be a mere bagatelle.
14. I do not know, but from ¼ to ½ lb. would I think be sufficient.
15. No, except that like all other plants it does better to be kept clean and the surface of the soil between the plants occasionally stirred.
16. I have never heard of manure being used, but doubtless the soil should be kept in heart to enable it to yield some three or four tons of green leaf containing more than a ton of fibre every year. I think that at least the refuse vegetable matter should be returned to the soil. Of course a periodical inundation would be a manuring.
17. The second year after planting the plant should be sufficiently grown to commence the cutting, but the crop should be increased in quantity year by year for some years afterwards.
18. The process of cropping is continuous; as the outer leaves of each section grow to maturity they are trimmed off and leave room for the immature leaves in the centre of section to grow.
19. The cropping would go on in Ceylon, I should think, nearly or quite the whole year round.
20. I do not know, and if a horse-hoe or scraper were used for weeding the manual labor would be very small.
21. The Phormium Tenax which is prepared for market for Europeans is dressed by machinery. The machinery is very simple, viz. revolving scrapers against which the Phormium Tenax is held by spring plates. The native process by hand is maceration in running water. The Maories prepare the best Phormium Tenax by a very tedious process: they take half leaf of the Phormium Tenax, cut through the layer of fibres lying in the inner part of the leaf with a sharp shell, leaving the outer layer of fibres (which are the finest and most free from gum) intact, then pressing the back of the leaf upon and over a bit of hoop iron, the inner layer of fibre is run off and thrown away, leaving the outer layer of fibre with fine epidermis of the leaf upon it. When this is dry the skin is easily knocked off from the fibre, and in this way the most valuable fibre only is secured, which is less than half of the fibre, the leaf contains. For the Sinhalese the separation of the fibre from the vegetable matter surrounding it would best be done by heating in running water.

22. I think England is the best market. The market value varies according to quality. At present the machine-cleaned flax is worth £18 to £20 per ton. It is always quoted in the *Home News*.

23. The market is unlimited.

A. FOLLETT HALCOMBE.

CACAO AND HELOPELTIS.

SIR,—Your correspondent "E. X. Z." from Uva, in sending specimens of Helopeltis, states that they operate upon the pods in such a way as to render them useless. I suspect he is confusing. Helopeltis will destroy very young pods, about the size of a little finger; but older pods they do not hurt, only disfigure the husk with spots. But many pods, this year, have turned black before reaching *full* maturity, though this is not the result of Helopeltis, and the cause is not yet quite ascertained. Most people, however, attribute it to the great drought, a certain percentage of cacao thus refusing to ripen, exactly similar to coffee. Every year, since coffee began, there has been a lot of light bean and, in dry years, branches, always where heavy bearing, lost one-third of their crop, by the ends dying and the crop blackening and falling.

CACAO.

TREATMENT OF THE TEA BUSH: MR. P. R. SHAND NI CORRECTION.

Coolbawn, Nawalapitiya, 17th April 1885.

DEAR SIR,—In your paper of yesterday's date I see a letter signed "Experience" in which the following statement occurs:—"In fact Mr. P. R. Shand of Strathellie is the only planter I ever heard of trimming his tea plants in the way described, and that was some years ago." "Experience" is wrong: I never treated tea bushes in the way he describes, and I never advocated such treatment. I have before me a letter which I cut out of your paper and which I wrote in May 1880 in answer to some remarks by "C. A. R." who *kindly* pointed out the mistakes of the *Ceylon* tea planter. From this letter I now quote:—"I quite agree with 'C. A. R.' in his remarks about allowing the plant to bush from the ground. Many acres of tea in Ceylon have been treated otherwise and had all the suckers pulled off the stems of the trees for years, on the advice of a gentleman of long experience in Assam, though most of those with a locally acquired *slight knowledge* did not follow out this plan."—Yours faithfully, P. R. SHAND.

TEA BULKING FACTORIES IN COLOMBO.

18th April, 1885.

DEAR SIR,—I have not got a copy of the letter I wrote to you about tea bulking factories in Colombo, but I am under the impression that I specially reserved the question as to whether such establishments for the final manipulation and packing of tea here would offer any advantages to tea planters beyond those which they now enjoy in being able to complete these operations on the estate.

The chief point dwelt on by me in that letter was the fact that as far as my experience went such operations might be carried out in Colombo with perfect safety to the tea, provided that proper precautions were taken at the Factory, and in the transport of tea from the estate. I agree with "S." in your issue of the 16th so far, that I think it would be difficult, if not impossible, for such establishments to earn a paying dividend without extra cost being entailed on proprietors; but I have by no means lost sight of the bulky nature of unsorted as compared with sorted tea. I deny, however, that it need be made to occupy double the space of the latter; and, even if it did occupy double the space, I deny that the *weight* of empty shooks would therefore necessarily be doubled. Thus the average weight of the shooks of a half-chest measuring 18 by 16 by 15, or 2·50 cubic feet, is 13 lb.; the average weight of the shooks of a whole chest made of the same wood and measuring 5 cubic feet, 24 by 20 by 18, being 23 lb. Besides, if it became the custom to send tea down in this way, I have little doubt that Government, with its usual far-seeing liberality in such matters, would grant a special rate for return shooks. There is however another way of sending down tea which I have seen tried, it was only in one instance however, and all I can say is that it came to no harm in that particular instance—as that is in bags. On the occasion I allude to, the tea arrived in single bags, in fine dry weather, and was immediately attended to, and, beyond being a little broken perhaps, and having gathered a few fibres which had detached themselves from the bag, I could detect no deterioration whatever. If however bags are employed at all, I think it would be better to have two, viz., an inner one of withering cloth or stout sheeting, and to enclose that in another of some waterproof material which could be so well fastened as to secure the tea against injury from any sudden atmospheric change.

Anyhow the saving which "S." grants might be effected in sorting the tea in Colombo, instead of on the estate, would in most instances, cover the cost of returning the empty shooks.

"S." says it is obvious that no saving would be effected in material, carriage, or labour. Now, as regards the first item, it is clear, that, if sorting were done in Colombo, the cost of machinery and carriage thereon could be saved to estates; also the cost of the fuel in final firing, and the labour employed thereon as well probably as the cost of a portion of the drying apparatus which would otherwise be required. Then, as regards the labour, it is not merely a question of a saving on the cost thereof, but of setting free a certain number of hands which with a rush of leaf coming forwards might be more profitably employed than in performing operations which could be done as efficiently and as cheaply, if not more cheaply, in Colombo. This is *the* point which will probably decide the question; but I am free to admit that it is one on which tea planters have a great pull over the coffee planter of a former, and even of the present, day.

"S." says that superintendents will prefer sorting their tea in the estate factory even when making in quantities too small for shipment. It may be that they will prefer it; but there is no absolute reason for the preference, beyond a natural desire to become acquainted with the best methods of sorting. I am constantly written to by people who sell me their tea to know beforehand how *I* wish it sorted; and, when I have replied, as I have in some cases, that if they liked they might send it unsorted, it always appeared to me that they were rather pleased than otherwise to be saved the expense and bother. As to the need for a single establishment in Colombo to manipulate the tea purchased at local sales, will you think it out of place for me to call attention to my advertisement in the local papers, from which it will be seen that such an establishment has been in operation for some time past? and, so far as I am aware, the results have been perfectly satisfactory to all concerned. Hitherto I have only bulked *different estates' teas together on my own account*, the teas of other proprietors having either merely passed through for shipment in the ordinary way or been bulked and packed ahu mark by itself; but I am now prepared to make up breaks by bulking and packing the produce of small gardens, or of large properties which are only commencing to produce leaf in small quantities, if I am instructed to do so. Each estate tea will, in that case, be separately valued on arrival; and teas of similar character will be bulked together in parcels sufficiently large to form sizable breaks for sale in London, the owners sharing pro rata in the nett proceeds.—I am, dear sir, yours faithfully, C. W. HORSFALL.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, March 26th, 1885.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
BEES' WAX, White	Slightly softish to good hard bright	£6 10s a £8
Yellow	Do. drossy & dark ditto	£5 10s a £6 5s

CEYLON PLANTING: SEEING THE TEA GROW: WITH A GLANCE AT CACAO, CARDAMOMS AND OTHER "NEW PRODUCTS."

(*Continued from page 866.*)

THE BLACKMAN AIR PROPELLER FOR CACAO PREPARATION AND FOR TEA DRYING—TEA ROLLERS AND DRIERS—INFRINGEMENTS OF PATENTS—THE SIROCCO AND THE AMERICAN FRUIT EVAPORATOR—STEAM *vs.* WATER POWER—SEMBAWATTE ESTATE—ROADS *vs.* RIVERS—SANDBANKS IN THE KELANI—A DREDGER NEEDED—A RAILWAY IN THE FUTURE—PRESENT NECESSITIES—PLENTY OF SINHALESE LABOUR AVAILABLE—DIFFERENCE BETWEEN TEA AND ITS PREDECESSORS—ARECANUT CULTIVATION—TEA ESTATES IN THE KELANI VALLEY—THE MAGNIFICENT SCENERY OF THE KELANI VALLEY—AWISAWELLA AND SITAWAKA—DANGERS FROM FLOODS—PROSPECT OF BRIDGES—RUWANWELLA IN 1814 AND 1885—MOSS IN THE LOW-COUNTRY AND ON THE HILLS—LIME AS A CURE FOR MOSS—MANURE AND ITS RESULTS—TEA ON OLD AND WORN COFFEE ESTATES—CTTLEA MANURE—EFFEC OF MANURE ON TEA—TEA ON PATANAS—INDIGENOUS ASSAM AT HIGH ALTITUDES—OLD TEA TREES IN DOLOSBAGE—ASSURED SUCCESS OF TEA IN CEYLON.

In my last series of notes, I promised to further notice the Blackman Air Propeller. I have mentioned what I saw of its performances at Kawudapelella, and certainly I could not help feeling that, even more than for cacao curing, it would be useful in regulating the temperature of tea factories. For instance, in moderating the tremendous heat, from which at Dunedin I had to fly, generated by Kinmond's blast drier, I was told that the coolies in attendance on the machine, required sometimes to use cumblies to soak the perspiration from their bodies. Heat is an excellent thing, but even of a good thing there may be too much. Kinmond's roller seems to err in the same direction as the drier, in generating too much heat. On this account and that of leaving too much leaf in a flat state, I heard that on two estates these rollers were to be abandoned in favour of Jackson's, which really seems to be as near perfection (except as to price) as any machine can be. The principle of Kinmond's roller is that of two discs facing each other and revolving perpendicularly. In Jackson's one part is superimposed on the other, and the action of the human hand is very closely imitated by the double action of table and box. I must state, however, that Mr. Thomas of Oonoonagalla was perfectly satisfied with the working of Kinmond's roller, stating that it only required to be carefully attended to, in order to give satisfaction. While on the subject of rollers, I may say that I saw in the course of my travels a Thomson's Challenge Roller, but that I heard nothing in favour of its "most peculiar" principle. It is driers, however, and not rollers which generate heat in a factory, and to moderate this heat or to send currents of air, or diffused air, hot or cold, through a manufacturing or withering house in damp or misty weather, the Blackman propeller would seem to be calculated to have a good effect. From a pamphlet, copy of which Mr. Ross favoured me with, I may take a few extracts indicating the nature and pretensions of the machine, which can be set in operation by hand or water-power as well as steam: in fact, it is described as "a mechanical contrivance for moving any quantity of air with a minimum of power." It is said to be in operation for the purposes of removing heat from engine and boiler rooms, &c.; foul air from breweries, &c.; steam from paper-mills, &c.; dust from rag-rooms of paper-mills, &c.: moisture from wool-driers, &c.; smoke from workshops, &c.; odour of cooking from restaurants, &c. After showing the importance of fresh air to human life and health, the pamphlet proceeds:—

It is, however, surprizing that so important a subject should be so little understood, and that it should have taken so long to learn that *Air will not*, any more than anything else, *move unless impelled*, [or drawn] and that to move it in any direction it is necessary *to apply force* acting in that direction. *How* to do this is the problem to be solved.

It is stated that fans have acted imperfectly, and that the Blackman air propeller, of which an engraving is given,

Is the result of continued and costly experiment. The blades are so formed, especially towards the periphery, that all radial and counter flow of air is prevented; the air is attracted or drawn in towards the whole of the supply surface, about 40 per cent. entering around the periphery and 60 per cent. on the side, and all the air thus operated on is impelled directly forward from the discharge side of the Propeller, almost without friction or waste of power.

The Propeller is so constructed that the whole of its surface is made use of either for the entrance or exit of air. The feed or supply area is as it ought to be, much larger than that for discharge. The form and position of each blade are such as have been found by experience to be best adapted for producing a maximum result under average circumstances.

The Blackman Air Propeller, therefore, moves very large volumes of air in a continuous straight column with comparatively little power, with a minimum of noise and friction, and against such an amount of resistance or "water-gauge," that it fulfils happily conditions most desired in Mechanical Ventilation.

It is very light, easily fixed, and can be placed in window, door, ceiling, side wall, floor, or any other convenient position. Where used for exhausting, or where a maximum effect is desired, it should revolve in the space to be ventilated, delivering the foul air to the outside immediately, or through a flue or shaft. The best results, in comparison with size and power required, are in practice most conveniently obtained by a 48-inch propeller, which presents a sectional surface of 12 square feet. The wheel being 8 inches deep, has a large feed surface, the dimensions of which are, the depth of wheel (8 inches) by its circumference (12 feet), equal to 8 superficial feet, and this, added to the 12 feet at the side, gives 20 feet of feed surface, and 12 feet of delivery surface for a 4-feet diameter propeller, which, when driven at 330 revolutions per minute, will move 15,000 cubic feet of air per minute, requiring rather less than one actual horse power. When driven at 570 revolutions per minute it will move 30 000 cubic feet, or 1,800,000 per hour, requiring 2¼ horse power. That is what the patentees say for the machine, and Mr. Ross spoke favourably of its performances, of which he afforded us an example. After stating what we know from the effect of punkahs to be true, that an atmosphere which is sultry and oppressive may be rendered cool and refreshing by merely setting it in motion, the letterpress proceeds:—

Arrangement of openings.—For successful ventilation it is necessary that there should be free entrance from the outer air, and free exit to it for all the air required: communication with a closed space, though large, will not serve the purpose.

Where it is important to avoid draughts the openings inward should be small, numerous, and distributed.

In all cases the collective area of such openings should be at least equal to that of a circle the same diameter as the Propeller used.

Leading facts.—Before proceeding to provide for ventilation it is necessary to take into account all the facts of each case, for example: Heated air rises to the ceiling, and heavier impurities, such as carbonic acid gas, remain near the floor; it is, therefore, desirable that the flow of air caused by the fan] should cross throughout the space

to be ventilated, say by entering near the floor and departing near the ceiling, or *vice versa*. as the case may be, carrying with it all the objectionable matter to be removed. The supply of air need not even if a portion of it be brought through the crevices about doors and windows, cause any unpleasant draught.

It should not be forgotten that air like other fluids, tends to move in the direction in which it meets with the least resistance, and that if a door or window be open near, it is vain to expect air to pass through distant and contracted apertures.

Direction of Currents.—As a rule, ascending currents are effective and free from objection; the Blackman Air Propeller, however, can be used to produce currents in any desired direction, ascending, descending, or otherwise.

In many cases where a maximum effect is not a primary object it may be found preferable that the Propeller, should force air into the building, placing the exits in either the top or the bottom storey, or wherever there is any vapour, odour, dust, or other impurity which it is desirable to isolate and expel.

With this arrangement there need not be any sensible draught in any apartment, the whole building ventilated being merely a vessel full of air running over at such a rate as will renew its contents any desired number of times per hour.

In buildings already erected, wherever a flue or air shaft can be found, and the required power be best applied, whether in garret or cellar, the Blackman Air Propeller can be placed, and satisfactory results obtained.

Examples are given of the removal of moisture from paper manufactories especially, and we could not help thinking of tea withering and manufacturing houses when we read :—"The propeller has effectually removed the vapour-laden atmosphere and supplied a pure, dry refreshing air." Anyone entering a tea-factory where tea is being rolled, fermented and roasted cannot but be struck with the strong general resemblance of the vapours to those of a brewery, and, therefore, we quote what is said in regard to the use of the machine in brewing establishments :—

Steam or damp air remaining in the tun room tends to rot, or set up fermentation in, the wood, which, in a still atmosphere, finds its way to the beer, and affects its keeping qualities. By using the Blackman Air Propeller this tendency is reduced to a minimum.

It removes carbonic acid fermenting cellars as it is generated, the temperature of the room is under control in all states of the weather, and bacterial germs are kept inactive.

Flies, amongst other pests, can be removed by the creation of a current of fresh air, and we are told that

Raw material or product of any kind can be cheaply and conveniently dried by using the Propeller, either in combination with heating apparatus or otherwise, and on this point the following facts are submitted :—

1. Substances are dried by either moisture being taken up by the surrounding air.

2. A large quantity of cool air will absorb more moisture than a small quantity of hot air.

3. With air of the same temperature the larger the volume of air coming in contact with the substance to be dried, the quicker the drying process.

Hence, if a simple means can be provided for moving large volumes of air quickly and cheaply, it will be of the greatest use in drying processes.

The Blackman Air Propeller meets this wants.

The pamphlet contains ample drawings and directions, and the machinery which would suffice for cacao or tea curing houses would not cost much money. Mr. Ross would probably give further information of his experience, and the London address is "The Blackman Air Propeller Ventilating Company, Limited, 57, Fore Street, London, E C." The copy of pamphlet from which we quote can be seen at the *Observer* Office. On Mipitiakande we found Mr. Morrison securing ventilation by means of open unglazed windows, simply with eaves over them: but this would scarcely answer in large establishments and in a different climate. We may mention that the fine tea on this estate, which is noted for the good prices it fetches in the London market, is provided as yet with only Kerr's hand-roller, which did very satisfactory work. At a subsequent period, a gentleman largely interested in tea said he would desire nothing better in his factories than Kerr's rollers. We saw the inventor in his home on Kinrara (a different estate to what we remember it in its glory in 1856, but evidently capable of regaining prosperity as a tea estate), and Mr. Kerr seemed determined to resist Mr. Jackson's threat of legal proceedings for invasion of patent. Where invasion of patent or principle begins or ends it, is difficult to say. Anyone looking at the new appliances added to Davidsen's sirocco, must see that the idea of the horizontal arrangement is borrowed from the American Evaporator which we were, we believe, the first in Ceylon to notice as probably suited for tea drying. We did not then think of cacao curing, to which Mr. Fraser of Wariapolla is adopting one of the American fruit driers. It is right that bona-fide inventors should be protected while giving the public the benefit of their ingenuity in combining and applying the principles of mechanics and engineering. *Our* business is to give the best and most correct information possible regarding useful machines and their performances. Except on the lowcountry estates, the expense of steam engines or of anything beyond good water-wheels for motive power ought to be seldom necessary in Ceylon. Apart from the cost and danger of working, the conveyance of steam engines to estates is often a terrible business. In passing up the Kelani Valley, although it was not our privilege to visit, we yet saw, as no traveller can help seeing, Sembawatte tea estate with its conspicuous precipitous slope. Some years ago, in welcoming a new superintendent to an estate in Dimbula, we told him he must be prepared for differences of level. He replied he had been accustomed on Sembawatte daily to vary the air he breathed by a difference of 2,000 feet elevation, so that our altitudes were child's play to him. Although one of the steepest and one of the wettest tea estates in Ceylon, Sembawatte grows fine tea and plenty of it. The report we heard was 800 lb. per diem being made. An engine being required, 150 coolies proved unequal to the conveyance of the boiler and an elephant had ultimately to be put in requisition. A good main road through a district is a grand convenience, and so is a navigable river, but easily traversed roads or paths to and through estates, any distance from the main line of communication, are of essential importance and must be provided at as early a date as possible. The really fine road which runs through the Kelani Valley and not far from the course of that noble river, was, I recollect the one great work of the kind during Sir George Anderson's rule, poor Ralph Tatham being in charge. It was little anticipated that the road would prove so great a help as it has done to the rapidly progressing and most promising tea enterprize of Ceylon. The Kelani is navigable, more or less for light craft, from Mutwal, Colombo, to Yatiyantota, and when coffee was in its prime a good deal of it went down, while rice came up by this route. The story of the gentleman who is universally known and esteemed in Ceylon as "Logie" was revived as we passed (not crossed) the well-known *tota* or ferry. In order to test the performances of the cart drivers, he is said to have assumed the character, for a trip, of a cart driver himself, report adding that he traversed the distance bare-footed.

Yatiyantota is likely again to become an important point, for water transit has advantages over all other in the matter of cheapness. There are countervailing

disadvantages, however. Property entrusted to boatmen is apt to be tampered with, sometimes entirely disappearing. Then, rivers, the Kelani beyond most, are apt to silt up, impeding or absolutely stopping navigation for lengthened periods. The tendency of the Kelani, which is especially slow-flowing in its lower course, to deposit silt and form sandbanks, has, we were told, greatly increased in consequence of the large clearances in recent years at its sources and along its sides. To such an extent is this the case that I was told of goods dispatched from Awisawella by boat which had not been heard of in Colombo on the eleventh day, the distance being not much over thirty miles. To aid the increasing traffic, it would seem that a dredger, always an expensive matter, must be employed by the projected Steam Company, if it is started, or by Government, who could recoup the expense by charging tolls. A railway from Colombo up the river valley must be relegated to the far future. It could be made, no doubt, but it would probably flood Colombo in the process, besides being itself liable to be washed away or breached by the frequent floods of the river, which rises in the near mountain ranges. A branch railway, from some point of the main line to the top of the valley, may also be thought of and carried out in the future, but what seems to be demanded at the present is such a programme as the following :—

1st. The keeping in good order of the road from Ginigathena Gap to Awisawella, and the portion of the Ratnapura road from the latter place to Colombo.

2nd. The improvement of the navigation of the Kelani river, between Yatiyantota and Colombo.

3rd. The bridging of the two beautifully romantic ferries of the Sitawaka and Kelani rivers.

4th. The completion of the road which, starting near Ruwanwella, is to have its terminus in Dolosbage. We were able to trace the course of this road from eminences in Mipitiakande and Dunedin and again from the heights above Gang Warily in Dolosbage, to its terminus in the beautiful valley below, and we cannot doubt the value of the work for native as well as European interests.

Native prosperity is now more than ever dependent on European enterprize, in consequence of the failure of coffee. Multitudes of Sinhalese are only too glad to obtain employment on tea estates. One planter in Dolosbage told me he could turn out 1,000 Sinhalese per diem, if he wished ; while a gentleman in Kandy stated, that, wanting Sinhalese labor for the conversion of an old coffee "totum" into a tea estate near Hunnasgiriya, he authorized his kangani to offer the usual wages of 33 cents. He was told that he could obtain an ample supply of labor at 30 cents per diem. There are two peculiarities about tea which distinguish it from its predecessors :—it offers no scope for the ingenuity of light-fingered Sinhalese, as picking green leaf will not pay, even if it could be well disposed of ; and a rainstorm, which so frequently, especially in recent years, proved fatal to coffee blossom, destroying the hope of fruit, has but slight influence if any on tea flush. *Apropos* of European and native interests, I may notice the recent discussion as to the cultivation by Europeans of the arecanut palm. The idea in the Kelani Valley is, evidently not new, for some of the estate paths, for instance on Dunedin, are lined with beautiful even rows of this most elegant of palms. But, of all things, its products, unlike those of the tea bush, would surely be liable to theft. As far as native interests are concerned, I was struck with two circumstances in being driven along the road in the neighbourhood of Ruwanwella : the abundance of thickly planted, luxuriant and fruitful grows of areca palms and the well-to-do appearance of the natives. The latter, it was easy to see, was the effect of the former. As we ascended towards Kitulgala, the areca palm disappeared, and, according to a fellow-traveller with whom I foregathered, their place, as subserving native interests, was taken by arrack shops planted at distances of only three miles apart ! This must surely have been a traveller's tale. The three estates I visited near the beautifully situated and neatly kept station of Awisawella were Avisawella, Elston and Penrith, each of more than 1,000 acres in extent, so that there is, on these, plenty room for expansion. We also visited and were hospitably received on Spring Vale and Brazennose, while Mipitiakande and Dunedin were the centres of our observations for two most pleasant (if hot) days, Mr. Morrison insisting on our planting a couple of tea bushes before saying farewell to his hospitable and flourishing domain. More or less closely we saw many other estates and groups of estates. Of the beauty, grandeur, fertility and hopeful promise for the future of the Kelani Valley, we have carried away the most vivid impressions, and it will give us pleasure if, besides best good wishes, we can contribute to the success of the Tea Enterprize here as elsewhere in the island.

We seemed to say farewell to the combined fertility, loveliness and grandeur of the Kelani Valley in our last, but, like the hero of a very different scene, we "oft say good-bye, but seem loth to depart." Certainly, I ought not to forget, amongst the estates visited, that of the genial and hospitable Mr. James Gibson where, amongst other interesting cultures, we saw what we suppose is the finest specimen in Ceylon of the scandent rubber plant, *Landolphia*. Neither can I forget how my progress upwards from Mipitikande to Kitulgala and beyond had so much additional interest imparted to it by the presence of a lady artist, with the enviable faculty of transferring to her portfolio the "counterfeit presentments" of scenes of beauty and grandeur amidst which I should have liked to linger as she and her husband did, when between Kitulgala and Ginigathena, the series of parallel ranges separated by the straight stretches of the Maskeliya and Kahelgamuwa gangas and the Dikoya (*dik oya*, the long river) which flow as they have flowed for ages, since the mountain waters first tore their way through the rocky ramparts behind which they had been so long pent up. During the journey, the reminiscences of which I am now recalling, I have from so many points of vantage luxuriated in scenery where the beautiful, the romantic and the grandly magnificent were combined, that I should hesitate greatly to give the preference to anyone of the many views of the mountain zone I enjoyed. But certainly as a view of and into the mountain ranges from the comparatively lowcountry, I do not suppose that in all Ceylon any combination of scenic attractiveness can surpass the look up the course of the Maskeliya and other long-stretching rivers to the neighbourhood of the sacred Peak and its surrounding guard of wooded mountain masses and rocky cliffs, streams flowing and torrents dashing over their sides, silvery waterfalls being conspicuous accessories of the scenery. Having been nearly half a century in Ceylon, without having travelled through the rich and varied scenery between Awisawella and Ginigathena, I can now only say that I feel glad of the new joy imparted to my life by the contemplation of so much of the glories of tropical nature. Awisawella itself, with its old fort, is an exceedingly pretty and interesting station, and as to the twin fords over the Kelani and Sitawaka rivers, a little beyond what will probably be known as "Tea Town," they present scenes so romantic that one ceases to wonder, that here Hindu legend placed the temporary dwelling place of the Oriental Helen, whose adventures in connection with those of her deified husband form the chief theme of the great Indian epic, the *Ramayana*. But river-fords, or ghauts as they are called in

India, although beautiful and romantic are inconvenient and sometimes dangerous, when the moisture of clouds deposited on the near-by mountains rushes down in resistless floods. Knowing as I do the amount of property and the number of lives sacrificed in former days at fords, I can keenly appreciate the value of the hundreds of bridges which now span most of the large and so many of the smaller rivers of Ceylon, and so I was glad to learn that there is prospect of fine iron bridges affording the Kelani Valley planters and others unimpeded passage over the Kelani and Sitawaka rivers. How different the state of things already, with the excellent road running through the Valley, to that which existed some seventy years ago, when the British troops had to toil over imperfect jungle paths, exposed to wet and leeches and malaria. The Ruwanwella fort, of which General Sir Robert Brownrigg laid the foundation in 1814, is an interesting memorial of the early days of British occupation, before the Kandyan kingdom ceased to be a power and became a mere name for an English Province. How the first commandant of Ruwanwella would have stared, had anyone vaticinated the time when, all fear of Kandyan aggression being over, the country around the military post would be converted into a series of flourishing tea estates. And this reminds me, that, whatever difficulties our friends in the lowcountry may encounter, they are not likely to have to contend with one disadvantage which attends tea culture in the high, damp altitudes of the mountain country. Up here we are finding the carpeting of thick, beautiful, velvety moss, which clothes the surface of the soil and on the principle of "the survival of the fittest" would, if let alone, extirpate all other weeds, a serious enemy of the tea tree. The moss, not contented with spreading over the surface of the ground, ascends the stems and clothes the branches of tea bushes. It first became necessary a short time ago, to send coolies round to rub the moss off the stems and branches of the tall seed-bearing trees, but now we find that the same process must be applied to a considerable proportion of the older bushes cultivated for leaf. When the moss clothes the stem and branches, the earth dashed up by rains is held in the embraces of the parasite, and takes its part in stopping the pores of the bark. Some years ago Mr. Elphinstone had the coffee on Logie cleared of moss and fungus (not the leaf pest but a dirty black growth) by means, we believe, of coir gloves which the coolies used. Gloves may not, probably, be needed in dealing with the tea bushes, but they certainly must be dealt with and the moss got rid of, from them and from the soil in which they grow, all except embankments which the moss helps to solidify. I had just expressed my conviction that lime, although not entering largely into plant composition, and being least of all required in any quantity by tea, would be the best remedy (with deep forking) for soil of good quality but mechanically stiff, in which coffee bushes had largely "died out," and also for eradicating the insidious moss, when I found my views fully confirmed in an article on Lime by Dr. Andrew P. Aitken, Chemist to the Highland and Agricultural Society. The entire article has been or will be, no doubt, reproduced in the *Observer*, or at any rate in the *Tropical Agriculturist*, but I now quote the passages which sustain my opinion in favour of caustic, that is burnt lime, improving clay soil and cremating weeds and moss. After showing that injudicious applications of lime may be injurious in producing nitrous acid and a consequent loss to the fertility of the soil, Dr. Aitken proceeds :—

But there are occasions when a cautery is needed, and when the application of caustic lime is of special benefit, *viz.*, where the surface of the land has become fouled by the growth of moss and feeble annual weeds. The strongly alkaline action of caustic lime is fatal to these superficial shallow-rooting plants, while it is unable to kill out, or do much injury to, the deeper-rooted plants such as clover and the more valuable grasses. Accordingly a fogged-up pasture is cleaned and improved by the application of caustic lime.

The phrase "a fogged-up pasture" is explained by the fact that in Scotland moss is spoken of frequently as "fog," while a fog in the atmosphere is known simply as mist. Dr. Aitken proceeds :—

There is another use of lime which has been long known, *viz.*, its power of decomposing and improving clay land. The influence of lime upon clay is very remarkable, and it is of a twofold character, partly physical and partly chemical. The chief defect of clay land is its tenacity and want of permeability in wet weather. It absorbs a limited quantity of rain, and then becomes slimy, and refuses to allow any more water to pass through it. The water collects in pools on the surface, or is run off the land as surface drainage. Land in this state is unfit to be touched in any way, and it requires the lapse of some days before it is dry enough to be in condition for working. If any portion of such a field had lime recently applied to it, it would be the first to dry up. The effect of putting lime on wet sticky clay is to cause the slimy surface of the clay to coagulate into little granular particles through which water can filter away. This is not altogether a mechanical process, but is due, in great measure to a chemical union between the lime and the clay, whereby an insoluable lime salt is produced, and the effect is similar to that observed when hard limey water acts upon soap. The slimy surface of the clay may be regarded as a kind of soap which becomes granular, in the same way as soap becomes curdy when acted on by lime-water. In order that a permanent improvement in the value of the soil may be achieved by this means, the quantity of lime must be very considerable, and where lime seems to have had very little effect in improving the condition of clay land, it is usually owing to the land having been lightly instead of heavily limed. Where clay soil has been derived from the disintegration of felspathic rocks, such as is common in coarse lands, it contains within it a large store of potash and when lime is applied to it, it unites with it, forming a lime clay, and sets free the potash, rendering it rapidly available for the use of crops which require potash largely, such as beans and other leguminous crops.

It is evident from what has been said regarding the action of lime in agriculture, that it is a powerful agent in the hands of the farmer, and its chief uses may be summed up under four heads:—

1st. It supplies an ingredient which is essential for the growth of plants, but it is seldom applied for that purpose, seeing that soils under ordinary cultivation usually contain far more lime than crops require.

2nd. It is a powerful cautery when applied hot to the soil, and kills out moss and surface weeds.

3rd. It hastens the rotting of organic matter, and is therefore beneficially applied to moss and moorland, and it also favours the production of nitric acid in the soil.

4th. When applied to clay land it decomposes silicates of potash, and improves the texture of the soil, rendering it more friable and permeable to water.

It seems clear, therefore, that although there is sufficient lime in our upland soils for tea, a moderate application of freshly burnt lime may be very useful to kill or prevent the growth of the prevalent and troublesome moss I have referred to, and that where soil is clayey and stiff or hard, a good dose of lime, with deep forking cannot but be useful. Tea, however, can pierce, by means of its powerful taproot and flourish in stiff clay soils, where cinchonas and even coffee had "died out." Then it becomes a question whether lime, added to cow-dung and other ammoniacal manures, may not be found absolutely necessary in enabling tea to flourish in soils very different to those in the lowcountry through which we recently passed and the high country in which we now write. Lawes

has shown that the effects of the application of cattle manure to the soil, in the temperate climate of Britain, have been evident for a score of years subsequent to the application. Now most of our old coffee plantations which have been thirty or forty years in existence and are now being converted into tea plantations, have had cattle and other manures applied to the soil for a score of years or more, and the question is, what proportion of fertilizing matter is retained by the soil of such estates, in the face of tropical combustion, tropical wash and the demands of successive crops of coffee and also of leaves, latterly to supply the want created by *Hemileia vastatrix* ? We have been asked with much anxiety, in the course of our travels, whether we could guarantee the success of tea on the soil of old and rather worn coffee estates. We could have no hesitation in answering such a question had it been preferred in regard to such old coffee land as that which we saw on Elkaduwa, on the Messrs. Hadden's estates, on Kandanuwara and places with similar soil. In other cases, and they are many, where the surface soil has been burnt or washed away, and the sub-soil did not look very promising, we naturally hesitated, only pointing to the wonderful growth of the tea plant even in such soil. Success in the cases referred to was explained as meaning an average yield of 300 lb. of tea per annum, and we know that, *by the aid of cattle manure*, that return has been obtained on soil in the Knuckles district which had previously borne coffee for half a century. The yield referred to has been obtained from comparatively young tea, so that probably, at from five to eight years of age, 300 lb. per acre may be obtained from the unmanured soil of old coffee plantations. But if the soil of a coffee estate is naturally poor and much washed, there seems little doubt that manuring *must* be resorted to. And we know that to ammoniacal manure, such as cattle-dung and other excreta, tea responds after a wonderful fashion. It is, we suppose, no longer a question that it did not pay, or but in rare cases, to keep cattle for the sole purpose of obtaining manure for coffee, and we should have thought that what held good of coffee would be true of tea. But evidently the question is not so simple as we supposed, for a gentleman, who has retained a good establishment of cattle from the era of coffee, told us a few days back that he intended to add to his establishment. As we saw old Madulkelly in the Knuckles recently, passing from the character of what was once a most profitable coffee estate, to the new and we trust equally profitable phase of a tea plantation, we could not help recalling the grand cattle establishment, which in 1856 (nearly a generation ago, alas !) Mr. Donald Stewart (the then superintendent, subsequently "King of Coorg") took justifiable pride in showing us, and we could not and cannot help believing that on Madulkelly and the many places similarly treated tea now planted or being planted will reap largely the benefit of manurial matter placed in the soil years ago for the benefit of coffee. May not the powerful taproot of the tea plant be capable of pumping up more than mere watery moisture from the lower strata which it reaches ? As is well-known, tea is being largely planted not only on old coffee estates, which have the advantages of roads, drains, bungalows and stores (the latter easily adapted) in readiness, and on chenas where coffee could be expected to give only a couple of crops, but on patanas or grass land. There are patanas and patanas, of course, and on good patana, there can be no doubt, tea will do well. But in Dolosbage a crucial experiment has been tried. Around the nucleus of an old coffee estate tea has been regularly planted on patana of all descriptions, to the extent of 300 acres. This enterprize is in the hands of a Colombo firm who must know what they are about and what can be done by means of liberal manuring. As a rule, however, tea is only cultivated on choice, good soiled patana of which there is much on the western side of the mountain zone, while it specially abounds on the eastern. The scope thus afforded for the extension of tea, where coffee was never thought of, is very great. I have been asked not only to guarantee the success of tea on old coffee land but to settle the question of the suitability of indigenous Assam tea plants for high altitudes. Besides questions addressed to me personally, the following letter has been forwarded to me :—

Lindula, 6th April 1885.

Sir,—Would you, or any of your readers, kindly give us the benefit of your experience as to indigenous tea ? how it answers in Ceylon ? up to what height it will flush satisfactorily ? and how it compares with high-class hybrid ? I have searched the *Tropical Agriculturist* through, but cannot (wonderful to relate !) find anything definite on the subject in that compendium of useful agricultural knowledge.—Yours faithfully, A PROPRIETOR.

We have several times stated, and we think our statements must have been transferred to the *Tropical Agriculturist*, that what we know of indigenous tea in Ceylon is that plants from seeds which were sent to us from Assam as indigenous made slow growth in comparison with first-class hybrid, at an elevation of 5,000 feet. But "planting weather," a most important element in the matter, may have been against us. We know that a patch of indigenous has done well at about 2,500 feet in Ambagamuwa, and respecting this we have no doubt Messrs. Leechman & Co. will give information. During our journeying we saw indigenous tea twice : first on the Messrs. Hadden's land, at an elevation not much under 3,000 feet, we should think ; and again on Mr. Fraser's land near Matale, at about 1,100 feet. In both cases the growth was vigorous, although, as a consequence of drought, the leaves had dropped from the points of the branches. This, we were assured, would be remedied with the setting-in of rainy weather, when luxuriance and progress would be very great. We could not help noticing the uniform type of large corrugated leaves in the case of these plants, so different to that of even the highest class hybrids, where there are great diversities in size and colour and appearance of leaf, although the golden green tinge prevails. While writing I recollect that I saw a few fine well-grown indigenous tea trees, being grown for seed bearers, on Gang Warily, but the elevation at which they were growing could not have been much above 2,000 feet. The only other *fact* I can mention in regard to indigenous tea is that a gentleman interested in the question of its growth at a high elevation visited Abbotsford recently, and expressed himself satisfied with the growth of plant which to those connected with the estate have been a disappointment. This seems the proper place to mention that on Mr, Blackett's estate of Pen-y-lan, in Dolosbage, I saw some of the original tea trees, either indigenous or first-class hybrid, grown by Mr. Lewellyn nearly 40 years ago. A slip taken from one of those trees about seven years ago is now itself a fine tall tree which has yielded and is yielding abundance of seed. But in days not so long gone by, so little appreciated was the enterprize which Mr. Lewellyn came so near to establish, that a good many of the fine old tea trees were cut down and converted into rafters for buildings ! It is curious to note how frequently an enterprize or a discovery—for instance, the finding of gold in Australia—is left in the tentative and doubtful stage, until the set time in the order of Providence has come. The success of tea in Ceylon was fully assured just as the fatal crisis in the history of

coffee had culminated. Those who think that this was mere accident cannot be congratulated on their mental idiosyncracy. Talking of indigenous tea, surely the splendid bushes on Windsor Forest must have been indigenous or very closely allied to "the real Simon Pure." We passed close to the grove of 50 acres of first-class hybrid seed-bearers on Kelvin which, we were told, have for some years yielded a return of from R45,000 to R50,000 per annum—in such request is good locally grown seed. Horagalla, which has also yielded so much seed of a high-class, we saw only at a distance with Seaforth and other estates of a fine and flourishing group. Tea has found its very home in Dolosbage, with the generally good soil and perfect climate of the district But of Dolosbage we must speak in a subsequent series of our (to ourselves, at least) pleasant recollections of a delightful journey.

TEA IN CEYLON IN DAYS OF OLD.

(*Notes from an Old Colonist.*)

Mr. Wm. Donnan (brother of your worthy Master Attendant) was really the first to introduce tea, south of Adam's Peak, and all suggested by a casual remark of an old Indian in Shand's office indicating how tea in poor soil had held its own against all the competing jungle plants and was found still in full possession after being for years abandoned, during the crisis—for there was a crisis in tea too. It was on hearing this that Donnan sent for seed to try on Barra. A poorer spot could hardly have been situated. Greig at first was *against* it and advised "stick to coffee," but he was ultimately won over.

Well done old Weyangawatte! It seems but the other day I was driving through it on one of my rounds, looking once more at its sapless shillellas, when who came hirpling out of the long deserted bungalow but old Corbet, who had just taken a sub-contract on the new line; he waved to me to stop: "What do *you* think of this leaf pest?" he asked, and added, "Do you know what Thwaites says? he declares that 15 years hence Ceylon (as far as coffee is concerned) will be a howling wilderness." A few days afterwards some fellow put this prophecy in print for the first time. It is now, alas, 15 years ago, and how fares it with coffee?

NOTES ON PROGRESS IN NORTH BORNEO.

(From *North Borneo Herald*, April 1st.)

A correspondent writes:—"On my last visit to Balhalla I was struck by a large number of small pieces of sponge apparently of good quality lying on the sea beach. I am of opinion, that, if the reef which cannot be far from Balhalla could be discovered, that sponges of a paying nature could easily be obtained."

On the 13th March twelve Malayas left Sandakan for the Segama River where they propose to prospect for gold on their own account, and being old miners from Sarawak, it is thought they will be able to make the venture a profitable one. The Commissioner of Lands, Mr. Henry Walker, who left Sandakan on the 26th ult. with some Chinese and Malays, has also gone up the Segama River and hopes during the dry weather which is now setting in to make such investigations as may tend to lead to the working by Chinese and others of the alluvial deposits of gold on a large scale. Before returning Mr. Walker proposes to visit the water-shed between the Segama and Kinabatangan rivers.

Among the various samples of Borneo produce which Captain R. D. Beeston has sent to Melbourne per the barque "Ellen" is one of the very valuable fossil or vegetable wax (*Mangkak-dangdarat*) which is stated on good authority to be the best lubricant for machinery that can be procured, and which combines economy with efficiency. There is no doubt but that this product if properly attended to will command a high price and be received with high favour in the Australian colonies, as, while it is as good as palm oil, its price will never run to anything like so high as that commodity, Captain Beeston thinks very highly of it, and has particularly requested his Melbourne friends to have it thoroughly tested. We shall be happy to hear the result of the experiment.

On the evening of February 2nd the barque "Ellen" of Newcastle, New South Wales, arrived here from Hongkong, bringing as passengers Captain R. D. Beeston and Mr. E. W. Thomas who are inaugurating a traffic in produce between Melbourne, Borneo and London. Captain Anthony made a fast passage of eight days from Hongkong, during thirty-two hours of which he was becalmed in the Mindoro Strait. As a proof of the facility of access to Sandakan harbours Captain Anthony sailed his vessel in after dark without lifting a tack or sheet and only hauled up his canvass on reaching his anchorage off the wharf. He sailed away bound direct to Melbourne with a cargo of soft wood timber on the 18th ultimo. He hopes to return shortly for another cargo, and we hope he will be able to do so as he expresses himself pleased with the country, and he possesses a thorough knowledge of the timber and timber trade.

THE RESOURCES OF NORTH BORNEO:

TIMBER.

That the future prosperity of Sabah must depend upon the introduction of outside capital, and the attention of outside capitalists, interested of course to their own ultimate profit, in its development, is a fact that admits of no adverse argument. Every individual, every country, and every community depends more or less on the principal of "give and take" to mutual advantage of each. Sabah possesses in itself resources which are practically illimitable, but to develop them, as they are capable of development, requires the attraction to the country of men, able and willing to put in their lot with, and further their own fortunes, while at the same time they are advancing the interest of the colony. It must be admitted, that, up to the present, outside enterprize in the country has been, to say the least, very limited. With the sole exception of the Chinese Sabah Land Farming Company no operations on any large scale have been attempted. True, the Australian Borneo Company started on a large scale, if taking up 100,000 acres of land may be classed as "operating"; but they have for over twelve months made no further sign, although it is probable their lethargy will be changed to activity within the next three months. The Deutsche Borneo Company are at work on Bangooy Island, but, with these three exceptions, outside enterprize in the way of planting can only be named on the *lucus a non lucendo* principle. With regard to the Australian Borneo Company, it must always be borne in mind that their primary object was taking up a large acreage for the purposes of sugar planting, and that, almost synchronous with the arrival of their agent in Borneo, sugar fell considerably in the market, so much so as to drive the sugar planters of Fiji and Queensland to the verge of despair; this being the case it is not perhaps to be wondered at that sugar "stank in the nostrils" of the Melbourne capitalists.

Mr. de Lissa, the pioneer sugar planter in Sabah, could do nothing in Melbourne in the way of raising capital to facilitate the growth of sweet cane on the banks of the Sagalind; but he discovered, what previously had apparently been quite unknown to him, that his land had a value in itself that did not require any planting to bring out. He discovered, or rather he was told, that the Seryah on his estate was a wood resembling very much the Queensland cedar which owing to the reckless denudation of the scrubs, and the absence of any conservancy regulations in that colony is rapidly becoming extinct. Samples of the wood submitted were approved of; a Syndicate was formed, and subject to the approval of an expert, Mr. de Lissa was offered a good price for his timber. The result is already known.

The expert, Mr. Stewart, is enthusiastic in his praises of Borneo timbers, and his enthusiasm has proved very catching in the great capital of Victoria. And now we come to the main point, or "bed rock" to use a digger's phrase, of this article, which is, that the timber trade will prove the first big enterprize which will bring about *bonâ fide* results between British North Borneo and Australia to the benefit of both Colonies. It is already known that the samples of the same timber shipped by the steamer "Woosung" are appreciated in Victoria, and if properly worked the Serayah of this country should take the place of the Queensland cedar, a wood which is nearly unprocurable at the present time. There is no hard wood in Australian colonies, not even "Jarrah," which will compare in durability to billian, while billian possesses two qualities which the "Jarrah" does not possess. It is ant proof, and proof against the attacks of the water worm. Therefore as a wood for sleepers and Australian railways, to be used in the construction of Australian wharves or from which to manufacture piles to be driven into the beds of Australian waters, billian is unequalled. There is a gentleman at present in Sandakan who has made it his business to make every enquiry into the capabilities of hardwood timbers, and who is empowered on behalf of powerful Victorian syndicates to secure a concession to cut timber on land in the colony. This gentleman has sent samples to Melbourne of billian, camphor, krueng and compas, and has also had cut and forwarded sleepers, made of billian, as specimens of what this wood is. He is confident that the timber once seen and tested in the colonies, the result will be the inauguration of a traffic between the two countries will develop into immense proportions. He is also engaged in the developing a trade in all sorts of produce and has sent samples of every item to Melbourne, but he maintains that the starting of the timber trade is but the thin end of the wedge towards establishing a trade, the proportions of will eventually grow to an extent which it is at present almost impossible to estimate.

CEYLON UPCOUNTRY PLANTING REPORT.

ANOTHER EVAPORATOR—THE WEATHER AND CROPS.

20th April 1885.

We are soon to have another evaporator in the field, built of galvanized iron. It is by an American firm "The Zimmerman Manufacturing Company of Cincinnati, who claim to have the exclusive right of using galvanized iron for evaporators secured to them by patent. This firm has been in correspondence with Ceylon, relative to their machine, and are having their drier modified to suit our requirements. As made at present, it has the great objection that it does not raise sufficient heat. This difficulty is however being overcome. It is something like the old style Sirocco, and about the same in cost, but has four times the capacity, and can be fitted with an apparatus for shifting the trays by machinery simultaneously and instantaneously.

The showery weather we are having is doing a world of good. Young tea, which was planted last year among the coffee, and since lately cleared, is growing in an astonishing manner, making up for the hanging-back of the dry weather in royal style. Cacao is full of blossom and looking well. Coffee does not seem to have set its blossom so well as it might have done: indeed I hear from some parts that it is altogether a miss. There are signs of the south-west monsoon approaching, and, if it be anything like a normal one, it will be a blessing to many, so much young tea depends upon it.

Iter Boreale Estate, Annatto Bay, Jamaica,
5th November 1884.

SUGAR is still king in Jamaica, for, although sugar in itself will hardly pay cost of cultivation and manufacture, rum will always sell well in the country at 1s 6d per gal., thereby saving freight and duty. Reduction of labour and expenditure is the order of the day on the sugar estates belting the sea coast round the island of Jamaica, and even the rum-drinking portion of the community have taken their departure to the Isthmus to assist in cutting the Panama Canal. Unfortunately many sugar estates have been abandoned: we hear of seventeen in the district of Vere, and many others abandoned years ago are turned into banana plantations. The old ruins of the mills and "great houses," barracks, &c., tell the sad tale of fallen greatness. Jamaica like Ceylon must make "an effort" and cultivate new products in time to meet the bad times in prospect; otherwise tropical agriculture here will be brought to a dead standstill. It is wicked to abandon a large property, and turn hundreds of people dependent on it to starve or break up their homes to seek other employment. It is the duty of absentee proprietors to continue the working of their estates even if obliged to borrow money in bad times of low prices of produce; otherwise it is "burying the talent in the ground." It is true a sugar estate requires capital to work it, but, when the expensive machinery is on the spot, and the estate possesses stock in abundance to draw the cane to the mills, only a few women are required to feed the "crusher," and, with one engineer and foreman of the boiling-house, a few men are required to boil the sugar; and the same with the still-house, very few men are required to attend to the distilling of rum, though it is necessary that those so employed thoroughly understand the *modus operandi*. On the estate from which I write, "Iter Boreale" near Annatto Bay, it is a pleasure to see the works in full swing, men heading out canes, "wain" men driving them into the "mill yard" stacked on end in a cart called a "wain" drawn by six stout steers, and four "wains" employing twenty-four head of cattle. The crusher is a very heavy piece of machinery driven by a steam engine. The cane is drawn in by the inward revolution of the two great cylinders, the cane-liquor running through a gutter into a cistern where it is pumped up into the boiling pans. Rum-making is a work of art, and considerable experience is a necessary to learn the different stages of fermentation. A cooper is required to head up the hogsheads of sugar and a carpenter or wheelwright to repair the carts or "wains" continually getting out of order. Coolies are useful carrying trash to the "trash-house," and bringing fuel to the engine fires, in which case "trash" is again useful.

BANANA CULTIVATION.—In Jamaica next to sugar, bananas rank second in command; in fact planters in the West Indies think seriously of substituting the banana for the sugarcane, unless prices of the latter go up sufficiently to show a margin of profit. The fluctuations in the prices of bananas hold the sugar planter in check: there is danger of glutting the market with bananas. Cultivation has been considerably extended of late years. Old sugar estates are now paying banana plantations, alive with traffic, cart and waggon loads of fruit driven down to help load every steamer calling. The creoles are fully alive to the profit derived from banana cultivation in the height of the season when over "eight-hand" bunches sell for a dollar or four shillings! As mentioned in a previous letter, No. 7 of this series, as many as forty thousand bunches were shipped in four vessels from our Atlas wharf at Port Antonio, and as many as one million bunches sent to the American markets of New York,—

Boston and Philadelphia, during the past year, valuing one hundred thousand pounds sterling The above is a low estimate as thousands of second class bunches are rejected and consigned to the "Hog Pen," or thrown overboard if carts cannot be spared to take them to the piggery. Fruit dealers and their agents are very particular as to the quality of the fruit. Bananas must not be harvested too soon, as "*thin fruit*" is rejected; then, again, bananas must not be "*too full*" for they would ripen too fast and probably rot on the passage to New York and other American fruit ports. Vessels from Jamaica take from five days to ten days on the passage according to the capacity of the steamer and navigators thereof, weather, &c. &c. Banana cultivation is likely to be the leading product of the island unless a great reduction takes place in sugar. Banana cultivation cannot be carried on in a slipshod manner, no half-measures will suffice to be successful, for, unless highly cultivated, the fruit will be inferior and quite unsaleable: a "*five or six hand*" bunch would be consigned to the pigs, and thrown overboard when the pigs have had enough; "*seven hand bunches*" are sometimes refused and always realize less per bunch than "*eight-hand bunches.*" With high cultivation, trenching, ploughing and frequent hoeings, 12 and 14 hand bunches are produced, more than a stout negro's load especially if "*full fruit.*" Sometimes we pack good specimen bunches for the Liverpool market in separate boxes to prevent bruising on the voyage, and the carts are always padded with dried banana "trash" (dead leaves). During the past busy season in the banana and fruit trade your correspondent gained considerable insight into the trade, and would recommend banana cultivation on a small scale combined with other products including cacao and coconuts to be a paying concern in Jamaica or any other part of the West Indies, the American markets being always open to a brisk trade.

COFFEE CULTIVATION.—The Blue Mountain coffee of Jamaica has always enjoyed a good name and fetched high prices in Liverpool; it still fetches fancy prices, but the cultivation of coffee compared to Ceylon is very second rate, nearly all the coffee estates being patchy, and weeded only three or four times a year; no draining done, and hence the patchy appearance; roads are very miserable, road tracers not in use, not known. Curing is well attended to, and a fair white sample of parchment coffee may be seen on most of the barbacues. The "works" on a coffee estate in Jamaica are the planter's pride: "Have you seen the 'works' on such and such an estate?" Well, what about the "works?" A great big empty stone store with walls of stone thick enough for fortifications, enormous drying grounds of massive mason work, terrace above terrace—to dry what? The days of large coffee crops are gone, the estates are worked on the "cheap and nasty" principle; therefore there is little prospect of improvement in quantity or quality under the present system of false economy. Take "Farm Hill," for instance, a large estate paying a European 14s per week and he lives in the store, whilst the bungalow is rotting for want of warming. Whitfield Hall, the next property, is better cared for, and Mr. McCrea takes an interest in his work, though he cannot make his fields look better than they are when only weeded quarterly or less frequently. The next "estate," "Abbey Green," is so patchy that one forgets he is walking through a coffee estate and requires all his eyes to keep on the "roads." Then comes "Radnor" with some good coffee bearing heavily round the bungalow and "works." Above this estate there are some good fields of coffee the property of Mr. Davidson,, but the coloured man who is called the "overseer" objected to my visiting it and disgusted me with his want of civility. From the abovementioned property there is nothing but scrub and yam patches until Mr. William Sabonadière's new purchased estate is reached, and as I arrived late and left early, can say nothing, good, bad, or indifferent, regarding it. Suffice it to say that my impressions of coffee culture in Jamaica are very *so-so* and that it would be difficult to make a silk purse out of a sow's ear. There is no extension of coffee cultivation in the Blue Mountains. Mr. George Henderson has bought up a lot of old properties and cleans them up where the coffee is still alive. He has one good field of pruned coffee called "Green Valley," and this little patch of good cultivation reminds everybody passing it what coffee might do under better treatment than it now receives on the Blue Mountains of Jamaica. Fancy my classing bananas before old King Coffee, but it is a melancholy fact that bananas receive more attention than the fragrant bean.

LIBERIAN COFFEE.—Liberian coffee would grow well here, and has been tried on a small scale. Considering that Arabian coffee grows well along the coast line, Liberian coffee would probably do better as it stands hot weather better. Some plants have been put down at Low Layton by Mr. Mason for Mr. Broughton and Mr. Janour of Priest's River beyond Port Antonio has planted a few.

COCOA OR CACAO.—As a proof that this plant is grown in Jamaica we drink our chocolate every morning, and agree with Linneus that it is "theobroma" (food for gods). As to the cultivation it is very scattered: a tree or two in this garden and a tree in that garden growing higgledy-piggledy with mangoes, oranges, coffea arabica and coconuts, breadfruits, &c., &c. The creole girls make it into sticks, and these they carry to market on Saturdays and sell for a "quatty" or three-halfpence. Cocoa or cacao plantations are few and far between: many people have a few shuck specimens of cacao plants struggling with the weeds under the too dense shade of bananas. As far as this cultivation is concerned it is a greater disappointment than coffea arabica and coffea liberica, because a Ceylon planter expects to find the West Indies the home of the cacao tree and finds to his soprise that Ceylon grows the article on a much more extensive scale and produces pods of better quality and size. Anyone can see at a glance that most cultivations in the West Indies are almost at a standstill, and Ceylon will most undoubtedly take the place of the West Indies in the production of cacao.

CINCHONA CULTIVATION.—People in Jamaica do not do things with a rush; hence the cinchona spec. is limited to a few small clearings, the Portland Gap Company taking the lead with a fine field of officinalis and a few Ledgerianas doing fairly well; their clearing would be better if drained, roaded and placed under European supervision. Mr. McCrea junior has opened 20 acres of officinalis: the plants are mere seedlings, and will take some time to grow into trees, especially as weeds grow faster than cinchona and choke the ground. Mr. Marshall (late of Ceylon) is wisely putting down cinchona and coffee in the same clearing in case of an accident. He has opened fifty acres and is knocking down another fifty at an elevation of 5,000 feet. Other planters have put in a few plants of officinalis and succirubra, and Mr. George Henderson is pushing on the growth of Ledgeriana plants obtained from the Government Plantations. If cinchona goes up in price, again the Jamaica cultivators will make money, for the climate and soil are both suitable for the growth of all varieties of cinchona.

TEA.—It is very strange that tea cultivation has never been thought of in Jamaica, with rainfall, climate, soil, elevation, in short everything in its favour. Hitherto there are no tea bushes but those in the Government gardens up in the Blue Mountains, and from these Mr. Mason of Low Layton and Mr. Forrest (late of Ceylon) obtained seed from Mr. D. Morris to try in Annatto Bay on "Iter boreale" and Low Layton near Buff Bay. The coast of Jamaica facing Cuba is suitable for tea growing, the rainfall being over 100 inches per annum and the soil good, with a forcing climate for the growth of flushes.

GINGER.—Jamaica ginger is a thing one hears much of, and sees less in the way of cultivation, the enterprize having nearly died out; still there is a limited cultivation of this valuable root, for ginger beer is made, and sold for 1½d and 3d per bottle, the former made of brown sugar and the latter with white. A stick called the "chew stick" is used to give it flavour and a festive appearance; the "chew stick" is also used by the creoles as a substitute for a tooth-brush, and fine specimens of sets of teeth the natives possess. The cultivation of ginger has fallen off in Jamaica of late years, and I have not seen any cultivation myself.

PIMENTO OR ALLSPICE.—This is an article of export and grows wild in parts of the island, and is said to be difficult to propagate; like the cacao, it grows mixed up with other products.

CINNAMON will grow and has been distributed, but is not an article of export. The chocolate is flavoured with cinnamon, therefore it must be known to the small farmers in Jamaica.

NUTMEGS.—There are a few nutmeg trees cultivated and small plantations of the same, but there is no export of nutmegs that I know of from Jamaica. In making a "Doctor" nutmeg is grated and mixed with the milk and rum to give it flavour, and it is a fashionable beverage.

PINEAPPLES.—Those who have cultivated pineapples have made money: in one instance brought to my notice, one hundred pounds an acre was the result of pineapple cultivation; £200 being made off two acres. The pineapples of Jamaica are sweet, though not large. Dr. Phillippo gained a prize lately at the Agri-Horticultural Show at Cumberland Pen of £1 for the best exhibits, but they were not equal to pineapples grown in Ceylon. The finest specimens of pineapples I ever saw in my life came from Porto Rico brought by a Spanish steamer to Port Antonio to load up bananas. Some of those large fruits (the Porto Rico pineapples) must have weighed from 8 to 12 lb. I did not taste them, so can say nothing about their quality. In the dry weather at Port Antonio I purchased small sweet Jamaica pines for 3d each. About 8,000 dozens are produced.

ORANGE CULTIVATION.—The orange flourishes all over Jamaica and fruit has been exported largely to America and England. Thirty or forty millions, worth about £40,000, are said to have been exported. This trade is not brisk as the quality of the orange varies so much and it is difficult of transport, one planter in the Blue Mountains telling me they did not pay him for the transport by mules, a day's journey from the shipping port of Kingston. We shipped a considerable quantity from Port Antonio to New York, carefully packed individually in soft paper, and forwarded in ventilated boxes.

SARSAPARILLA.—It is a subject for surprise that this article is not much cultivated, considering that the far-famed Jamaica sarsaparilla is thought to be the genuine article only, yet in Ceylon about Matale district, sarsaparilla grows like a weed, a pretty little creeper with a silvery striped leaf. It is used as a cooling beverage and well known as one of the best blood-purifying root-extracts.

ANNATTO SEEDS.—The annatto seed is used as a dye and is in great demand, judging from advertisements frequently appearing in Jamaica newspapers by merchant shippers and dealers in produce. About 132,000 lb., valuing £1,400, is the output of this article, Annatto Bay from where I write is probably named after the above.

LOGWOOD.—Logwood is plentiful round the east and north coasts of Jamaica and shipped in great quantities. Although quoted at £5 per ton, the price paid for it here is only sixteen shillings per ton, the cost of felling, clearing, carting to the shipping port and freight to America or England bringing it up to £5 per ton. It is one of those things that would not pay a private individual to embark in unless he held a large contract to supply a firm who would send their vessels periodically for a cargo. The logwood dealer would then be in a position to purchase at the highest rate. The exports of logwood are said to be about 30,000 tons, worth about £90,000, or at £5 per ton £150,000. The tree is not indigenous to Jamaica, but was introduced from Honduras by Dr. Barham, and is used largely in colouring cheap clarets and other wines and spirits. It now grows wild about Port Antonio and Annatto Bay, from both of which shipping ports it is shipped.

FIBRE AND FIBRE MACHINES.—Fibre-producing plants have been cultivated on a small scale, and Dr. Phillippo drew the attention of Government some time ago to the new industry. I have mislaid his valuable paper on the subject, but, should it turn up, I will forward it on to you. Last year at the Agri-Horticultural Show at Cumberland Pen, a Fibre Machine invented by Mr. Kennedy of Jamaica was worked by steam and shown to do clean work, a number of samples of fibre being very highly spoken of by the judges of samples. Ramie or Chinese grass and Agave Americana, with the common aloe, were all put to the test, and I believe some samples of pineapple fibre, and plantain &c. Price of the machine is £27.

OTHER USEFUL TIMBERS.—There is another dyewood called "Fustic," of which 3,500 tons were shipped worth about £10,000. "Dogwood" is a hard timber used for cart-wheels and other purposes. Mahogany furniture is often met with, including tables with pieces of great width bearing a high polish and therefore very valuable. The English oak may be seen in the Blue Mountains. On Whitfield Hall estate, there are two oak trees, one very much larger than the other, about thirty feet high and about 120 feet in circumference of foliage, the trunk being about six feet in circumference near the ground. Tamarind trees are plentiful and of great service as shade trees and the fruit for making a healthy cooling beverage mixed with sugar and water.

COCONUT PALMS.—There are extensive coconut estates round the sea coast of Jamaica. The properties opened up by Dr. Ferguson are the best on this side (facing Cuba), north and east coasts. The export of coconuts is very great, millions of nuts being shipped from Port Antonio and Kingston. The palm flourishes everywhere near the sea, and most sugar estates have a few thousand trees along the seaboard and "Negro House" fields; they are, however, subject to the ravages of rats, and occasional hurricanes bend their proud feathery heads to the ground never to rise again. Drinking nuts are sold at three farthings each, and ripe nuts at 6s per hundred. The coconut palm is always a feature in tropical scenery, and extremely useful to the natives for food, rope, and matting. The coconut is not utilized in so many ways here as in Ceylon and India, and it is surprising that coconut oil is not one of the leading exports of Jamaica produce.

BREADFRUIT TREES now in season (October and November). The breadfruit tree is another friend of the people and much liked, cooked in various ways. I need not enlarge on the beauty of the tree, it having been so often described by travellers. Suffice it to say, they are plentiful in Jamaica growing side by side with the far-famed mango tree.

MANGO TREE.—The creoles almost live on mangoes for three months, June, July and August. There are so many kinds, that it is difficult to select them in the order of their respective merits as to quality. The celebrated number eleven ranks first on the long list, the above being free from stringy fibre like some of the more juicy kinds. All sorts of stories are afloat regarding the number eleven mango. Some "old time" negroes (who remember slavery) say Lord Nelson brought them ashore from his ship, and others say they were landed by Captain Cook. Whoever landed them did the Jamaicans a good turn, and your correspondent will always gratefully remember the number eleven mango of Jamaica. The turpentine mango is very juicy and is an acquired taste. Some do not like it as well as the kidney mango; both are acceptable in the dry months of June, July, and August. The mango trees have spread all over the island of Jamaica varying in quality according to cultivation, even those in pens doing well, because the stock shelter themselves and pay their footing with a deposit of rich manure. The largest mango trees in the world, I firmly believe, are to be found in Jamaica and other West Indian islands, ranging from three, four, five, six, and even seven feet diameter, and perhaps over one hundred years old, planted in the days of slavery. We exported mangoes from Port Antonio to New York and to Liverpool, carefully wrapped up in the same way as the oranges, and dispatched in light ventilated boxes.

THE AVOCADO PEAR.—You people in Ceylon do not know what is good until you have eaten the avocado pear with your beefsteak and potatoes. It is gathered green, ripened in the corn, and sliced up for the table at every meal in Jamaica as long as it is in season, a favourite dish of the creole; he lives on "pears." When ready for eating, it is soft.

VEGETABLE CULTIVATION.—Coco yam (*Caladium esculenta*) is the staff of life added to white and yellow yams, breadfruit and pears, but any kind of English vegetable can be grown according to elevation: green peas, Irish potatoes, tomatoes, lettuce, cabbages, radishes, onions, vegetable marrow, cucumbers, &c., were all doing well in the Blue Mountains, and, when looking round the garden at Whitfield Hall, I came upon an apple tree in bearing and a fig tree with a lot of figs ripening: Mr. McCrea takes care of his garden. He pointed out some thirty or forty English apple trees. Mr. and Mrs. Stephens and Mrs. Chisholm pride themselves on their garden too at Radnor

estate. I admired their flowers and shrubbery. Violets do well both at Radnor and Whitfield Hall, and a great number of roses of good varieties were to be seen in these two well-kept flower gardens in the Blue Mountains.

THE TREE TOMATO.—I must not forget to mention the *tree tomato* growing to a height of from *six* to *ten feet* and bearing fruit the size of an egg with a scarlet skin; it is used as a salad and not long been introduced from South America. I kept some seeds, and put them down in Port Antonio, but the crabs disturbed the bed and they had not germinated up to the time I left that district.

SKILLION CULTIVATION.—A kind of onion or leek called by the creoles "Skillion" or "Skellion" is largely cultivated for the Kingston market: several acres in patches may be seen near Farm Hill on the first range of the Blue Mountains.

WATERCRESS grows wild in the streams. I gathered some between Radnor and Abbey Green of fine growth, and saw it growing in many other places in all parts of Jamaica, both in the mountains and in the lowcountry near the sea.

CULTIVATED ENGLISH FLOWERS.—English roses, violets, strawberries, dahlias, gladeolas, tuberoses, geraniums, pinks and carnations, Virginian stock, mignonette, colius, jasmine, begonias, gloxinias, gesnarias, daisies, zinias, and many others too numerous to mention, were met with, between Kingston and Gordontown, the handsome bougainvillea and honeysuckle with Cape jasmine and other climbing plants ornamented the entrances of country villas and cottages.

WILD FLOWERS OF JAMAICA.—The jungles of Jamaica are liberal in the distribution of wild flowers, the large pink begonia the most imposing, the convolvulus, moon-flower, trumpet-flower, oleander, marvel of Peru, or 4 o'clock-plant of many colours, the mamosa or sensitive-plant, which shrinks and folds its diminutive leaves when touched, Indian "forget-me-not" plants quite worthy of cultivation in the most artistic garden or rockery, all these beautiful things are shaded by a wild growth of rose and star-apple trees with mango, orange and pear trees, pointing to the fact that all that part of the country between Gordontown and the Blue Mountains has been cultivated and cared for.

FERNS OF JAMAICA.—There are said to be as many as five hundred distinct varieties of ferns in this island, and very lovely they are too: the "maidenhair" fern is a great favourite. I have not seen a list of them, to compare notes with your Ceylon collection, or those of the Straits.

WILD STRAWBERRIES.—When journeying from the Blue Mountains by a different route to Port Antonio, I was delighted with the plentiful supply of wild strawberries growing on the banks over the bridle-path from the Government gardens, and feasted on the wild strawberries until a heavy shower of rain urged me forward, on what proved to be rather a long and tiring journey, from 5,000 feet (five thousand feet) elevation down to the sea shore, before dinner on the same day! Those who visit Jamaica in the fruit season would be delighted with the treat in store for them as far as fruit is concerned. It is a pity that just now a cloud of depression hangs over the whole of the fair islands in the West Indies. Nothing is paying good returns for cultivation, and sugar, coffee, cinchona, fruit, &c., are all at a temporary discount. Let us hope there will be a speedy reaction. Jamaica should do as Ceylon has done, try all products, suitable to climate and soil, and extend those most sought after.

I must conclude my remarks on the tropical agriculture of Jamaica, as this letter is extra long, and trust that what information has been given will be of service to both the readers of the *Ceylon Observer* and the *Tropical Agriculturist*, and remain, sir, yours faithfully,

HENRY COTTAM.

MR. JACKSON is greatly pleased, we understand, with the Kadawella Tea Factory, Ambagamuwa, Ceylon, the equal of which in accommodation and convenience he thinks is not to be found on many Indian plantations in India. In Assam, factories are as a rule much lower, precautions having to be taken to guard against a collapse from earthquakes among other risks.

PLANTING IN NEW GUINEA AND NETHERLANDS INDIA.

(*Translated for the "Straits Times."*)

Land in New Guinea.—Through the Consul-General for the Netherlands in Australia, John Strachan has sent in an application to the Java Government for granting him a concession to turn 350,000 acres of land to account lying in that portion of New Guinea which belongs to the Netherlands. The Government has directed the Head of the department concerned to report on the application.

A correspondent writes to us as follows from Batavia:—As you have already been informed by telegraph, the Government, has granted to the Geographical Society of Amsterdam a subsidy of ten thousand guilders to meet the expenses of scientific researches in the Western portion of New Guinea. From what I can gather that society has been informed that should the finances allow of it a like amount will for the present be put in the estimates every year for the purpose.—*Samarang Locomotief.*

The *Java Bode* of the 10th March asserts that Mr. A. W. Remmert, an expert, has just invented a steam sugar evaporation apparatus both compact and simple in construction. It is said to be not only cheap but also advantageous to planters from its combining saving of expense in labour, fuel, and machinery with better quality and larger quantity of the product turned out. Fuller particulars are not as yet available. The Sugar cane disease known by the name of *Sereh* continues to spread steadily, it being met with in Java wherever black and red canes are grown, but generally in a sporadic form. White and yellow cane is found to be almost free from it, but the cultivation of these varieties, however advisable on that account, is attended with such difficulties in consequence of their being less hardy and calling for great care in cultivating than the others so liable to the disease, that they are at present chiefly grown by natives. There is every prospect of one of the burdens weighing down the sugar growing interest there being shortly lightened considerably by the Netherlands India Railway Company agreeing, subject to Government sanction, to lower its freight rates on low grade sugars.

According to the Sourabaya *Courant* the coffee leaf-disease was continuing to gain ground in Java, every remedy suggested having failed on trial, including that of lighting large fires on the estates to fumigate the coffee trees. At a meeting of coffee planters held recently at that city has decided in consequence of low prices and hard times to lower wages on their plantations 20 per cent. thereby following an example already set elsewhere in Java.

ANTIDOTE FOR SERPENTS' VENOM.

In your issue of August 21st, Mr. John Williamson speaks of the healing virtues of the plantain leaf for rattlesnake bites. Another remedy, which is, perhaps, not so easily obtainable, but sure to have a beneficial effect if taken immediately after the bite, is simply a quart flask, or, if possible, what is yet better, a two quart flask of good whisky, into which is put about a handful of pounded sassafras root. Shake thoroughly, cork tightly, and you have ready for immediate use one of the most powerful as well as certain expellants of snake venom that is known. It should be taken not only internally but externally as well by an application immediately to the wound.

Of this valuable remedy I learned when on a trout-fishing excursion through Sullivan country. I had returned home tired, wet and hungry, to the cabin of my backwoods host, and had just prepared my fish to become a "party of the second part" in a trout supper when, happening by mere chance to look on

what in a more modern structure would be known as the mantle, my eyes fell upon two very interesting objects. The first was a set of rattles, which numbered fifteen; the second was the dried skin of an enormous copperhead. Of course, I asked the old man to tell me all about it, and he very willingly unbosomed himself. He said that in the fall of 1877 he was hunting deer, and was creeping through the bushes endeavoring to flank a large buck when, without any other warning than the usual rattle, a rattlesnake one of the largest of its species, sprang upon him, sinking its fangs deep into his leg. Quick as thought he killed it with his hunting knife, bound tightly the limb above and below the wound and made hasty tracks for his cabin. Arriving there, he applied the whisky and sassafras root in the manner previously described, and in about ten days he had recovered.

On another occasion he was out trapping, when he was attacked by a copperhead, which bit him in the big toe of his left foot. This bite was treated to the same dose and in the same manner, and speedy recovery followed, while the skin and rattles were kept as trophies of his two snake adventures.

I also know a woman who was bitten in the foot while at the spring getting water, and who after using the remedy, recovered fully and in a very short space of time.—C. A. R.

In her book "Snakes, Curiosities and Wonders of Serpent Life," Miss Catharine C. Hopley writes on the subject of "The Venoms and their remedies," as follows :—

"To conceive of an antidote to snake poison in the true sense of the term," Sir John Fayrer explains, "one must imagine a substance so subtle as to follow, overtake and neutralize the venom in the blood ; one that shall have the power of counteracting and neutralizing the deadly influence it has exerted on the vital forces. Such a substance has still to be found, and our present experience of the action of drugs does not lead to hopeful anticipation that we shall find it."

With regard to the many drugs used in various countries for the cure of snake bite, it is curious to note that, as a rule, they are procured from the most deadly plants. As like cures like, so poison cures poison. Pennyroyal, says Charas, was held to the nose of a viper, who, by turning and wriggling, labored hard to avoid it, and in half-an-hour's time was killed by it. This was in July, at which season these creatures are computed to be in the greatest vigor of their poison.

Another drug which is poison to a venomous snake is tobacco, within the reach of most persons. This, among native remedies, has always been in favor, and we have heard of its efficacy ever since the weed was known to Europeans.

Strychnine appears to have a similar effect to tobacco on snakes. Fayrer found cobras extremely susceptible to the influence of strychnine. An almost impalpable quantity caused a cobra to twist itself up in a rigid series of coils and die. Carbolic acid is another drug which produces powerful effects. Poured on the floor of their cages it will kill venomous snakes in a very short time. A large Bungarus died in ten minutes in this way.

Dr. Weir Mitchell approves of carbolic acid. The *Lancet* recommends every backwoodsman to supply himself with a little of it, which is easily portable and manageable in capillary tubes. In several of Mitchell's experiments with crotalus venom, carbolic acid applied to the wound was attended with success. But it must be done at once.

The whole secret of cures when cures can be effected at all, lies in promptness. It is celerity on the part of the Indians which insures their success. In an instant, if his comrade be bitten, the savage is on his knees sucking the wound, grasping the limb firmly or strapping it tightly above and below the bite, knowing quite well the importance of checking the circulation. He has his "poison pills," and tobacco in his pouch. He explodes gunpowder on the wound and loses not an instant, nor does the victim lose heart. He submits with courage and confidence, and in these lies another element of success.

Many cases are on record of persons being at death's door through fear alone, when bitten by a harmless snake, but recovering on being assured that there was no danger. And other cases are well known where bitten persons have died of fright and the depressing influence surrounding the accident, when they might possibly have recovered.

And now for a few words about the most popular and perhaps the most attainable of all remedies—alcohol. No wonder that the backwoodsman resorts to this, which without any chopping-off of fingers or toes, or personal pyrotechnics, or other local tortures, deadens his sensibilities, renders him unconscious of all suffering, and sends him into a happy obliviousness of danger. It is not a refined mode of treatment, nor one that presents many opportunities of exhibiting professional skill ; and it is no doubt somewhat derogatory to admit that to become dead drunk is an effective victory against snake venom. During a sojourn in Iowa some years ago, when wild and uncleaned lands formed the "streets" of the town in which I was staying—Lyons, on the Mississippi river, and as lovely a spot as artists and botanists can wish to revel in—it was by no means an infrequent occurrence to hear of rattlesnake bites.

"What was to be done to the man ? Is he alive ?" were questions naturally asked.

"He drank a quart of raw whisky and got dead drunk."

Generally a quart had the desired effect, that is, of causing intoxication. Persons unused to intoxicants might be affected by a less quantity, but so violent is the combat between venom and whisky that a large dose must be allowed before any effects at all are produced. I heard of a man in Nevada, George Terhune, a teamster (I give his name, having reason to believe the truth of the story) who was bitten in the hand by a rattlesnake while stooping to reach some water out of a spring. The man was alone and far away for human habitations. It was an instinctive and momentary business first to kill the snake ; then rushing to his wagon, he drew the bung from a keg of whisky and took a large draught of the contents. After swallowing as much as he could, he took some tobacco from his pocket, saturated that with whisky, and applied this poultice to his hand. He then proceeded with his team, drinking whisky at intervals, until he reached a dwelling, when he removed the poultice and found that the wound had turned green. Applying another of the same kind, he resumed his journey and his potent doses, reaching his destination the next day as sober as a judge, having imbibed enough fire-water to intoxicate a dozen men.

The quantity sometimes swallowed under such circumstances is utterly incredible. Professor Halford describes a snake-bite, near Melbourne, in which two bottles of brandy were drunk without any symptoms of intoxication, and another of a girl of fourteen, who, when bitten by an Australian snake, drank three bottles without being intoxicated. She recovered.

Alcohol has powerful attractions for oxygen, writes Professor Halford, on the theory that the venom has produced foreign cells in the blood ; so that if alcohol engage the oxygen absorbed by the poison, the cells sperish and recovery ensues. Dr. Shortt, of Madras says : Bring the patient under the influence of intoxication as speedily as possible ; make him drunk and

keep him drunk until the virus is overcome. Dr. Weir Mitchell states that delicate women and young children under the influence of snake poison could take quarts of brandy without injury, and almost without effect. One man—a man of temperate habits—took one quart and a half pint of brandy, which only slightly intoxicated him for about four hours. An other man bitten in the throat, was cured at the end of twenty-four hours, during which time he had two quarts of whisky in one night, and renewed, as the pulse fell, besides red pepper and other stimulants.—*Forest and Stream.*

NEW PRODUCTS: KOLANUT, GUTTAPERCHA, &c.

Mr. T. Christy has just published another number of "New Commercial Plants and Drugs," and a copy will reach you herewith. It contains a great deal of information that will interest your readers, European and native, planting and mercantile, and I may be allowed to mention just one or two points here. You know that Mr. Christy was instrumental in first obtaining fresh seeds of kolanut from West Africa, and in distributing seeds and plants to Kew and the Botanical Gardens of India and the Colonies. He has also paid great attention to the question of the properties of the nut and its utilization on a commercial scale. For this latter he seems to have been eminently successful, and he confidently recommends planters who own low-lying steamy land with plenty of moisture to cultivate the tree extensively, as he is sure that the demand for the produce in civilized countries will increase year by year. He says that "It is much more easily cultivated than ordinary cocoa, and yields a large crop twice a year; it does well in low steamy lands, and gives large crops of fruit in our West Indian Islands. The kola tree will flourish well at elevations lower than 1,000 feet, and even at the sea-level produces crops in the fourth year from planting the seed, and full crops from the tenth year estimated at 120 to 150 lb., the gathering of the crops being rendered easy by the natural drooping of the branches." He adds instructions for preparing and packing the nuts for shipment, but there is time enough for these by and bye, so far as Ceylon is concerned. His reason for comparing the cultivation of kola with that of cocoa is that a paste prepared from the kolanut has recently been discovered to be in itself superior to cocoa, whilst a mixture of it with the latter improves its quality immensely, rendering even inferior kinds equal to the best Caracas. Chocolate made with kola paste is, Mr. Christy asserts, ten times more nutritious than that prepared with cocoa, and he goes so far as to say that a workman can on a single cup of it taken at breakfast-time go on with his work through the day without feeling fatigued or hungry. All this, mind you, is not mere theory, but the result of actual experience. Our Government has been induced to try kola chocolate for troops on active service, and if it should prove equally successful in their case it is certain that there will be an enormous demand for it. I think Mr. Christy is justified therefore in his advice to planters, and those of Ceylon, who have shown such enterprize in regard to other products, ought not to be behindhand with this one.

Referring to the scarcity of guttapercha and the likelihood that at no distant date the supply from present sources will still further diminish, Mr. Christy mentions Dr. Trimen's identification of Gutta Sundek as *Payena Leerii*, and suggests that it is suitable for swampy land near the coast even where water is salt. There must be abundance of such land in Ceylon which might thus be turned to account, as the difficulty of extracting the gutta-juice from the bark may be got over by stripping off alternate layers of bark, pounding it, and then boiling it in water. This tree is of more rapid growth than the ordinary guttapercha found wild in Brazil and North Borneo, but no information is given as to the date at which it would first be fit for stripping.

Mr. D. Morris, whose annual report on the Jamaica Gardens and Plantations will also reach you by this mail, says that kolanut plants are now widely distributed in Jamaica, and its cultivation is being extended in the hope that ultimately kolanuts may be a recognized article of commerce. Locally the nuts are used as a stomachic and a tonic. They are said to have effected very remarkable cures in dyspepsia and allied disorders, and are used for this purpose in the same manner as cocoa or chocolate.

I am surprized to find, by the way, that Mr. Morris, in recommending Jamaica planters to extend cinchona cultivation, argues that their soil and climate are far more suitable than those of Ceylon, though he is obliged to admit that the Ledgeriana plants under his care have not been a success. He also gives expression to very exaggerated notions about the extent to which cinchona is dying out in Ceylon, and predicts that the industry there will speedily collapse. You will doubtless be able to correct him on several points in this section of his report, which is otherwise a most creditable document.—*London Com. Cor.*

THE *T. A.*—The Secretary of the Agri-Horticultural Society's Gardens, Madras, writes:—"We greatly value and appreciate it [the *Tropical Agriculturist*] and should much regret anything which might deprive us of it."

AVENUE TREES IN COLOMBO.—M. E. Loulié, Municipal Engineer, Pondicherry, writes to us:—"Six years ago when I was in Ceylon I found the avenues of your town planted with some very handsome trees. If you know any book or pamphlet treating upon avenue planting in general or at Colombo in particular I shall be much obliged to you by kindly giving me the name of the publisher and value of the books if possible." Mr. Wm. Ferguson has promised to send M. Loulié a copy of his pamphlet on Ceylon timber trees. It is curious that Pondicherry should appeal to Colombo in this matter.

THE LAST "NEW PRODUCT."—At the present day, with the numerous obstacles that exist to the profitable cultivation of tea and coffee in India, planters cannot afford to neglect any new means of adding to their incomes; and as the cultivation of the coca plant promises, from all accounts, to produce this desirable result it is probable that the attention drawn to it by Dr. Bidie's interesting lecture will not be allowed to die out. We hope soon to hear of coca plants and seeds being distributed in the various planting districts, and of experiments in the cultivation being made on a tolerably large scale. In the February number of the *Tropical Agriculturist* the editor has, with great industry, compiled a mass of useful information on the subject, and given a very full account of the history, cultivation and scientific value of coca (or as he would prefer to call it "cachuca.")—*Madras Mail.*

CEYLON TEAS IN LONDON.—A gentleman connected with the Tea Trade in the "Lane" writes under date 2nd April:—"I beg to acknowledge with thanks the March number of the *Tropical Agriculturist*, which contains much interesting information. I note with pleasure that you were able to make use of an extract from a recent communication of mine. Our tea market has been in a very firm state during the last three weeks owing to the anticipation of a rise in the duty. The enquiry for Ceylon teas has continued, and some desirable parcels have been sold at decidedly remunerative rates. A small lot of Blackstone teas brought the good average of 1s 10¾d per lb. These are very good teas having a fairly twisted leaf, good tip, and being well fermented. Another invoice from the Gallebodde estate also brought satisfactory prices, although I hear that the quality of the teas is hardly equal to former shipments. I notice that a few packages of Ceylon teas sold lately have been papered, flowered and figured after the Chinese manner. This hardly seems to me necessary, as dealers will not be influenced by the tea outside of the packages, but by the quality of the within.'

COCAINE, COMMERCIALLY.

Cocaine can hardly be said yet to have become a commercial article. The medical profession are taking a keen interest in it, but the price at present almost prohibits experiments, and naturally prevents it being taken into stock. The following remarks, collected from a couple of interviews, may be found of interest :—

Messrs. Allen & Hanbury say :—

"Demand for this continues brisk, and as there is no expectation of the arrival of new leaves in any considerable quantity till April, and stocks held are very small, the price of the alkaloid is likely to again advance.

"Moreover, the demand for this article in America is so great that, when there is any quantity of alkaloid to offer, it will be speedily bought up.

"Present trade prices are :—For 1 gramme, original bottle, 25s; for small quantities, 1s 9d. per grain.

"The application of this remedy becomes daily more comprehensive, and its success in different branches of mediciae and surgery more and more marked. There can be no doubt of its permanent establishment as one of the most valuable articles in the materia medica, and especially as regards its physiological action.

"Our medical journals and those of foreign countries almost in every issue note some new application of cocaine, and prognosticate an unlimited utility for it. It can be used with such an entire freedom from danger that in many operations it is preferable on all points as an anæsthetic to any other that can be employed.

"Not its least value, moreover, is in the fact that many operations formerly employing two practitioners can now be completed single-handed. Among the recent notices of its application are a number of supplementary cases in ophthalmics, some in aural surgery, naso-laryngeal surgery, urethral, vaginal, and rectal surgery, while it has been successfully applied in dentistry and as a remedy for severe neuralgia.

"It is still mainly used in solution of the muriate, but solutions of the citrate, salicylate, and alkaloid are also used. A preparation in ointment form is much used, especially in cases of severe surface pain, where considerable absorption is required. Solutions in oleic acid, oil of cloves, &c., are also employed in such cases. It may be noted that the aqueous solutions of the salts of the alkaloid (excepting salicylate) do not keep more than two or three weeks."

Mr. Martindale conversed as follows :—

"Makers' price has rapidly risen from 5s. to 21s. per gramme. Most of that used is made by Merck. Some of Petit's has been sold, and in this country Morson and Tanner have made a little. The stock of coca leaves in Europe now is very low, and, besides, old leaves do not yield nearly so much alkaloid as new ones. You can taste growing leaves in the Royal Botanic Gardens now (with the permission of the authorities). Fresh leaves leave a little sting, something like aconite; old leaves more resemble pure tea.

"The normal price for coca leaves in Peru has varied from about 1s. to 4s. per lb. It will probably be three or four months before we get a good stock here, though it is understood that some considerable quantity is expected in about six weeks.

TEA IN CENTRAL ASIA.

It is satisfactory to note that the exports of Indian tea by land have very largely increased during the year 1883-84. Tea to the value of Rl,62,293 went to Cabul in the past year, while in 1882-83 the value amounted only to Rl,39,286. But while this is satisfactory, there are certain elements in the trade with Cabul and Central Asia, which, to Indian traders generally, and specially to the tea traders, are very much the reverse. It is stated that a Russian Company is now being organised at Tashkend, which is demanding a concession for the purpose of supplying green tea to Turkistan at a lower price than that for which it can be imported *viâ* Cabul, and the Company claims that the arrangement will save the people of Khiva and Bokhara from the charges they have at present to submit to at the hands of Afghan and English traders. Apparently in Russia the authorities realise the importance of the Central Asian tea trade, and leave no stone unturned to drive out the competition of China and of India. It was noticed some years ago that the Khanates and Central Asia generally furnished an ever-increasing demand for tea, and that in a country like Bokhara, where the proverb runs "that a man drinks tea or dies," there was a great opening for exploiting Indian teas. But according to the *Moscow Gazette* of the 8th November 1883, Russia was equally alive to the fact, and a regulation passed for the refunding of the duties levied on tea passing through Kiakhta and Siberia to Central Asia, coupled with the Anglo-Afghan war, which put a stop to the passage of Indian teas through Afghanistan, gave an impetus to the Russian trade which is now thoroughly established. The Chinese merchants, too, unable to compete with them, have left the trade in Russian hands. In the same paper it is stated that improvement in the Russian trade is looked for by putting a check upon the smuggling of Anglo-Indian teas, and the article concludes with the remark that "the tea trade affords too large an item of profit in the Russian Central Asian trade to allow of any neglect in the application of measures for its retention in Russian hands." So that Indian exporters have to congratulate themselves at present on the fact that the Russian frontier is difficult to protect, and that for some years a trade may linger on promoted by smugglers. But that Russia should reduce her duties on Anglo-Indian teas is scarcely to be expected, for she can at once point to her general customs tariff and show that Indian teas pay no more duty on entering Russian territory in Central Asia than would be exacted on the same teas entering her frontier in Europe. So far the outlook for the extension of the India tea trade in Central Asia is gloomy, but gloomier still is a report which comes from Russia on the subject of the efforts now being made—with the strong support of the Government—to establish the cultivation of tea in the Trans-Caucasian provinces on such a scale as to enable the growers to compete with the Himalayan planters in Central Asia. It is hard to indicate in what direction counter-efforts should be made by the trade in India. The reduction in prices is no doubt the cause of the recovery in the trade to Cabul, and there seems no reason why our trade, as far as Cabul is concerned, should for the present decrease. Beyond, the Indian trader must trust to low cost of production, for no diminution in Russian duties can be looked for.—*Pioneer*. [Utterly impossible.—ED.]

TREE PLANTING IN SOUTH AUSTRALIA.

We have received a Government paper containing two reports from Mr. J. E. Brown, the Conservator of Forests in South Australia—the first containing suggestions for the planting of olives and mulberries on the mallee lands, and of dates in the Far North; and the second relating to wattle cultivation in the colony generally. Mr. Brown estimates that the scrub land could be put under olive cultivation for about £6 an acre, and an ordinary fenced land for about 30s. to 40s. The planting of the white mulberry would cost little more. A very good suggestion is made that the Government should plant a hundred trees of both kinds in every district of the colony, to show the residents of each whether or not the trees would grow in their locality. Mr. Brown also recommends that an experiment should be made as to the planting of trees in the northern districts. A plan is appended, showing the country up to the dividing line between South Australia proper and the Northern Territory, on which are marked the localities possessing fresh-water springs, and the areas of available land in their proximity, more or less in extent, on which it is estimated the date would probably flourish. The climate of the Far North is so like that of the indigenous habitat of the date tree that it seems to promise well for the maturation of the fruit, which does not ripen near Adelaide, though the tree grows there fairly well. A sum of £500, carefully expended, would, in Mr. Brown's opinion, be sufficient to test the practicability of providing "date *oases*" in the northern country, which, if successful, as he rightly says, would "secure one more step in subjecting these semi-desert lands to the ameliorating influences of civilisatiaon."

But of more importance than the foregoing are the suggestions as to the cultivation of "wattles." The trees known as wattles in Australia are indigenous species of

Acacia. These yield a bark rich in tannic acid, and for a time were a source of much profit to the colony. Owing to the improvident habit of stripping the trees wherever found, without any care as to keeping up the supply by new growth, the yield of wattle bark has fallen off to an alarming extent. The natural forests have almost disappeared, and of late years the trees have hardly ever been allowed to attain maturity. Trees two or three years old have been stripped; and hence the market value of the bark has been seriously diminished, though, as Mr. Brown says, "no bark or other material has yet been found in any quantity which contains a percentage of tannic acid equal to that of the broad-leaved wattle, of which South Australia is the principal habitat." The decrease in quantity and value of wattle bark is a serious evil to English and Continental tanneries. It is, therefore, unmistakably evident how important for the colony is the restoration of this important product. Two species are available for cultivation—the Accacia pycnantha, or broad-leaved wattle, which may reach 25 ft. or more in height, and a foot in diameter; and the A. decurrens, or black wattle, which grows to a height of 40 ft. or 50 ft., and to a diameter of 20 in. Not so rich in tannin as the broad-leaved wattle, it is yet reckoned that 1½ lb. of A. decurrens bark is equal in its tanning results to 5 lb. of English oak bark. There are two other species named, but of minor importance. Mr. Brown enters into copious details as to the management of wattle inclosures, and among other things notices the curious fact that the wattle springs up abundantly after bush fires, though naturally the seed may remain in the ground for several years before its husk is sufficiently saturated to allow germination to take place. Hence apparently was suggested the plan of subjecting the seed before sowing to the operation of a slow fire, so as to slightly crack the extremely hard outer covering without injuring the embryo. Soaking in hot water from 150° to 212°, and even boiling for one to seven minutes, were also found effectual, the seeds germinating in about three weeks. Supposing that the seeding has been properly accomplished, and the young plants properly attended to, Mr. Brown reckons that with an average of 1,000 trees to the acre, and bark at £5 per ton, there should be at the end of seven years, on 100 acres, a clear profit of £1,100. There are three or four other tan-yielding trees indicated as suitable for cultivation; but at present the likelihood of their being utilised seems small.—*Field.*

NOTES ON SILK-PRODUCING BOMBYCES REARED IN 1884.

BY ALFRED WAILLY.

Attacus atlas.—No success whatever was obtained with this species; at least, there was no possibility of obtaining fertile ova for the rearing of the larvæ. From a few cocoons of the large Himalaya race, which I had left from the year 1883, two female moths emerged; the first, on the 6th of July, was an imperfect specimen; the second, a perfect and splendid specimen, emerged on the 21st of July. From a number of cocoons of the Ceylon race, three moths only were obtained; a female on the 4th of September, a male on the 9th, and another male on the 20th of the same month. A small case of *Atlas* cocoons, which I received on the 25th of September, contained, to my great surprise, the largest proportionate number of live cocoons I ever recived from that tropical country; the cocoons which had not hatched, and they were in a majority, are the largest I ever received from Ceylon; the larvæ were reared on growing cinnamon trees. On the contrary, a case containing 111 cocoons, received on the 13th of November from the same country, only contained a few live cocoons, all the others having hatched during the voyage. The box was full of broken wings and dust.

On the 18th November, 1884, I received from my correspondent in Ceylon two most interesting letters on the rearing of *Attacus atlas*, and *Antheræa mylitta*, from which I shall reproduce the most important communications, some being from my correspondent's wife, who this year has conducted the rearing with the greatest ability and success. Writing on the 12th of October, my correspondent says:—"The *Atlas* cocoons I sent you are better than those previously sent, as the larvæ were reared on growing cinnamon bushes under a net in the open air, whereas the previous ones had been kept all their life on cut *milnea* branches inserted in water. The latter plan does well enough for the production of cocoons for manufacturing purposes, but the moths are not so large and strong as when the larvæ have been kept on growing trees. There would be no question about its being better for any purpose to feed the larvæ on growing trees, were it not that in this country it is indispensable to cover the trees with netting, and it is doubtful if it would be remunerative to cover in a whole plantation that way. You will observe that the cinnamon seems to produce a silk of superior quality to other trees. I have always thought the silk of the *Atlas* better than that of the *Mylitta*, if the former could only be utilised; I had almost despaired of ever being able to make anything of it, because *Atlas* cocoons cannot be reeled, and they are so tough in their natural state, that they would break the teeth of a carding machine. Only a week ago, however, I did succeed in drawing out the silk from the *Atlas* cocoon, and it was more by accident than by good management that I found out how to do it. Some time ago I boiled, with carbonate of soda, some empty *Atlas* cocoons along with *Mylitta* ones containing pupæ that had been long dead, and were quite dried up. The *Mylitta* cocoons were softened by the boiling, but the *Atlas* ones remained unmanageable; so I put the latter in a stoppered bottle to steep in the water they had been boiled in. I examined them after some days, and the steeping had not had any effect on them. Then I forgot about them for two or three months, and I found them last week after I thought they had been thrown away long age. They smelt very nasty, but they were quite soft, so that the fibre could be easily drawn out. I do not know whether the effect was due to the carbonate of soda or the decoction of *Mylitta* pupæ, or if prolonged steeping in pure water would have had the same result; but whatever the cause may have been, the effect was very satisfactory. I send you a sample, and if you pull out the silk from the open end of a *Tussur* cocoon, and compare the two samples, you will see that the *Atlas* is more soft and lustrous than the *Tussur*. The *Atlas* is dark in colour, but the colour is not in the silk itself, as it is quite white when it comes from the mouth of the silkworm, and is stained by the fluid which the insect discharges upon it afterwards, so that it could be made white by bleaching. Only four cocoons are required to produce the quantity of silk in the sample sent. The *Atlas* moth is more easily bred than the *Tussur*, as the larvæ do not move about so much, and the moths are very quiet, allowing themselves to be handled and carried about without attempting to fly away."—*Journal of the Society of Arts.*

VIOLET CULTURE.

Locality and soil have undoubtedly much to do with the success obtainable in the culture of violets, for in one place they may flourish, while in another they require skill and much coaxing to bring them to anything like perfection. One thing, however, is certain, viz., that growing violets in crowded beds, where the crowns get but little light and air, is not likely to favour the production of flowers. See how violets grow naturally, and you will gain a pretty correct knowledge of what they, in one point at least, require. Nature has given them the means of avoiding overcrowding, and of insuring to each plant a position favourable to its welfare. By means of the creeping stem, the young plant which is commencing life on its own account is removed far enough away from its fellows to admit of the enjoyment of a plenteous amount of light, air, and even sunshine, and seedlings continually springing up provide against deterioration of constitutional vigour. This leads one to think that violets might be very easily grown from seed, and that, where the usual means of cultivating them is not satisfactory, this method of doing so might be worthy of attention. Everyone knows how primroses and some other hardy flowers may be grown in much perfection on soils not naturally favourable to them, when a practice is made of raising them from seed

every year or so. Why, then, should we not grow violets in the same way? For all I know, they may be thus grown, but I never remember to have seen the practice recommended. One objection to it is, that the kinds would not come quite true, but I believe that violets are less liable to sport than many things; and even if they did, it would not in a general way matter much, and there would always be a chance of getting something new.

A certain amount of shade from the hot summer sun would seem to constitute an element of success in violet culture. At the same time, violets thrive very well in certain places grown as a field crop, and in the full blaze of the sun. This is, however, only where the soil is naturally favourable, being, generally speaking, a loam of a somewhat holding but otherwise free nature. The greater amount of fresh pure air, too, enjoyed in an open field tempers the heat of the sun and robs it of its debilitating effect. The violet often pines and dies in small gardens, because the atmosphere becomes overheated and deprived of its life-giving properties. It is, therefore, advisable in such places to select a position screened from the midday sun. Having my choice, I would prefer a border where the sun came until about twelve or one o'clock, as in July and August, which are the most trying months for violets, the most drying time of the day is during the early hours of the afternoon. Thus placed, and watered overhead about four o'clock, the plants are, in a great measure, guarded against the exhausting effects of a fierce sun and an arid atmosphere. The north sides of trees or of a building are often recommended as the most suitable position for violets, and in the southern counties they are probably very favourable places, as in warm districts and on light soils red spider is so difficult to grapple with in hot summer, when the plants are in the fierce sun throughout the day. In a north aspect, on the contrary, it is seldom troublesome. As a rule, however, I should be inclined to depend upon a deep root run in well stirred and enriched ground, in conjunction with a mulch of rotten manure and copious waterings and frequent sprinklings overhead to keep the insect at bay. If it does attack very vigorous plants, it rarely becomes their master. It is only debilitated specimens that are ruined by its ravages. Certainly in the northern districts of this country I would not preferably make violet plantations in a north aspect, but rather where the sun comes during the greater portion of the day.

There are two ways of making new violet plantations. Either the old plants may be divided after flowering, or the young runners can be taken when they have become fairly well rooted. Where the plants have not become crowded, and there is sufficient space for the plants to form nice balls of fibres before removal, they will, if carefully transplanted, scarcely miss the moving, and, if well attended to, will grow into large specimens by late autumn. If, however, they are likely to be crowded, it is better to cut them off and dibble them in in fine soil in a shady position, keeping the soil moist until they are well enough rooted to go into their permanent quarters. Old plants should be divided and set out in rows 1 ft. apart and 6 in. from plant to plant as soon as the blooming time is over, then they make good-sized specimens full of buds by autumn. When grown in frames they should be placed there early in October, so as to get good root-hold by winter. Violets in pots are very acceptable for the window and greenhouse; only a few flowers will fill a good-sized room with delicious fragrance.—*Field.*

TEA MADE FROM VACCINIUM ARCTOSTAPHYLOS.

BY W. T. THISELTON DYER, F.R.S.,
Assistant Director, Royal Gardens, Kew.

Mr. Holmes's note in the *Pharmaceutical Journal* (Jan. 17, pp. 573—4) pretty well exhausts the history of this curious product. But it will be convenient to record in the same pages the few other facts that have come under our notice at Kew.

In 1877, Mr. George Maw, F.L.S., brought from Asia Minor a small sample of the tea obtained at Broussa in Anatolia. Mr. Maw informed us that it was sold for about 8*d.* per pound, and he ascertained that it was made from *Vaccinium Arctostaphylos* (see 'Kew Report,' 1877, p. 45). Mr. Holmes mentions on the authority of Mr. Allen that in Lazistan and Tredizond it was first made in 1877: but in that year, at any rate in Anatolia, its use seems to have been sufficiently common to attract Mr. Maw's attention.

The tea next came under our notice in the Report by Consul Billotti "On the Town and Port of Samsoon, and on the Circassian Colony in the district."* Mr. Biliotti states that the Circassian families "consume large quantities of sugar, and have introduced the use of tea; but there being a sort of native tea produced at Amassia and Tokat, the yearly importation of this article from Great Britain does not exceed 1,500 pounds." We thought it was worth while drawing the attention of the Foreign Office to the matter, with a view of ascertaining the nature of this tea-substitute. Mr. Biliotti took a good deal of trouble, and obtained and forwarded to Kew specimens of tea and of the plant producing it from Amassia and Tokat, in the province of Roum, and also from Rizeh in Trebizond. Writing from Trebizond, he says:—"As it grows profusely here wild on high mountains (not below an altitude of 500 feet, so far as I have been able to ascertain), it would be of invaluable advantage for the population to know whether the plant belongs to the genus Tea, and whether cultivation would improve the quality of the tea now produced, which lacks in flavour. This may also be due to the natives using unskilful means for drying the leaves."

The tea sent had exactly the appearance and aroma of coarse black tea; so much so, that the Customs authorities insisted on charging duty upon it.

The specimens sent were identified by Professor Oliver as *Vaccinium Arctostaphylos*, without hesitation. He remarks that the plant is figured by Tournefort in his 'Voyage in the Levant;' but though that traveller mentions the taste of the leaves, he says nothing about its being used as tea. This confirms what Mr. Holmes says as to its use for this purpose being a practice of recent date.

The Board of Trade to whom samples of the tea were communicated, submitted them to Messrs. George White & Co, the well-known firm of tea brokers. They remark that common China tea, selling 5½*d.* to 6*d.* per pound, shows better value in every respect, and the admixture of the "Trebizond tea" could hardly reduce the cost, while it would certainly not improve its flavour.

Though the aroma of the "Trebizond tea" was so agreeable, the taste of a decoction was harsh and mawkish, with no appreciable resemblance to that of true tea. I sent a sample to Dr. Schorlemmer, of Owens College, Manchester, who has paid some attention to the chemistry of tea-substitutes. *Ledum palustre*, belonging to the next natural family, *Ericaceæ*, yields Labrador tea, and it seems odd that two nearly related plants should be pitched upon in such distant parts of the world for the same purpose, if there were no physiological basis for their selection. But I have not heard whether Dr. Schorlemmer has detected any principle in Trebizond tea which would account for its extensive use.

Since the above was in type we have been favoured by the Board of Trade with a copy of a memorandum (dated January 15, 1885) by M. Numa Doulcet, H.M. Vice-Consul at Samsoon.

I append a transalation which, I think, finally exhausts the subject:—

1. The tea in question became a commercial article in 1880; at first its consumption was limited to the country and particularly to those districts in which Circassian colonies had been founded.

2. It is manufactured by Circassian planters in the neighbourhood of Amassia, Tokat and Horck, all in the province of Roum, at a short distance from the forest which clothes the mountain chain called Beldagh, and on which the plant which furnishes the tea in question grows in great abundance.

3. I have not been able to ascertain the process of manufacture which takes place within the houses of the

* 'Commercial Reports from Her Majesty's Consuls, 1884,' Part 1, p 147.

Circassian colonists who undertake this industry, and who appear to be pretty numerous.

4. There are several gatherings of tea; that which yields the best quality takes place in May. About 5,000 ocques, (the ocque=2¾ lb.) are actually manufactured annually, but this quantity could be considerably augmented if there were occasion for it.

5. At the time of gathering the plant is in a shrubby state.

6. The tea is sold on the spot at about five piastres per ocque. The cost of transport to Samsoon might amount to about one piastre, which brings the price per ocque to six piastres in that town.

7. The consumption is almost limited to the requirements of the Vilayets of Sivaz (Roum) and Angora (Anatolia). It is to the town bearing the last-mentioned name that the greater part of the crop is sent. In 1881 a consignment was sent to France, but the transaction was not a profitable one. Some further consignments to Constantinople also do not appear to have been successful.—*Pharmaceutical Journal.*

THE CULTIVATION OF ROSES.

[With reference to the following extracts, see the remarks under "Market Gardening" on pages 842-43.—ED.]

Roses are subject to the attacks of many insects. One of the worst, and in some seasons the most troublesome, is a small grub that establishes itself in the foliage and causes it to curl, and also eats its way into the centre of the flower buds. The only sure and effectual way that we have found of eradicating them is to search the plants diligently when they make their first appearance and destroy them between the thumb and first finger. This is rather a disagreeable method, but it is a certain one, and a fine Rose bloom that might otherwise be destroyed is worth the trouble required. Red spider can be kept down by a free use of the syringe, but if the plants are properly treated this will give very little if any trouble until after the plants have flowered. Aphides are readily destroyed by a weak solution of tobacco water directly they appear. This insect if allowed to become established soon arrests the growth of the plants, and in a very short time completes its work of destruction. Mildew is perhaps the worst enemy the grower of Roses has to contend with. The solution of softsoap and water which I have recommended so frequently in these pages as a preventive is the cheapest and best that can be used for the purpose. Nothing else is used here, and mildew does not trouble us, but the solution is applied every time the plants are syringed, and when properly used and at the strength I have already recommended, it will not injure even the delicate petals of the Rose. If the plants are allowed to become badly infested, this mixture is not strong enough to destroy mildew, and if a very strong solution of softsoap and water is applied, it will not only injure the blooms, but the foliage as well. None of the mildew compositions in the market is of any use in destroying this pest until the cause has been found, such as dryness at the root or cold draughts, for if they destroy the mildew upon the plants it will appear again as if by magic. Strict attention to the requirements of the plants and the softsoap solution as a preventive will enable the grower of Roses to have them annually without mildew. The softsoap solution and the way in which it is mixed and used I give again for the benefit of new readers. Four pounds of softsoap are boiled in an old saucepan for twenty minutes, about one quart of water being added. This after being boiled is mixed in a vessel kept for the purpose with four gallons of water, soft water being preferable. About half a pint of this solution is stirred into each four-gallon can of tepid water every time syringing is done. The plants are not syringed with this solution at intervals of a week or a few days, but daily, and sometimes twice in the day when the weather is favourable. In addition to its use as a preventive of mildew, it assists wonderfully in keeping red spider in check and renders fumigations for aphides seldom necessary. It also acts as a gentle stimulant, and imparts a fine dark glossy hue to the foliage.—WM. BARDNEY.—*Journal of Horticulture.*

TRENCHING GARDEN SOIL.

Mr. Iggulden did good service in bringing the above subject before your readers. I thought, when reading his first article upon the waste of time in deep cultivation, that for weeks our Journal would be filled with the valuable experience of able correspondents. As the old saying goes, "every little will help," so I will give a little of my experience, and I am prompted to do so by Mr. Temple's excellent article on page 104, when he mentions a new garden in which I was employed in the west of England twenty-seven years ago. The site was chosen partly because it was a convenient distance from the house, and partly because there was a small old garden there before; but apart from these advantages the site was most objectionable, as it was with an extraordinary cost of labour that it was brought into anything like uniformity. A great part of the garden had to be raised 6 or 7 feet, and in other parts sandstone rock had to be excavated to the depth of 10 feet. Many of your readers will doubtless say, What has all this to do with trenching? which I will now try to describe.

In the low ground before mentioned a trench was opened 2 feet wide to utilise the stone and get it out of the way. About 12 inches of this stone was thrown loosely into the bottom of the trench. As the work proceeded a stiff marly clay has brought from the frame ground and other places where soil was not needed. This was mixed with the surface soil of the plot of ground and raised to the necessary height, trenches being partly filled with stone until the whole ground was finished and prepared for a crop. I might say that here I had considerable practice with pickaxe and wheelbarrow, both of which I have since found useful, and when the "chief" was out of the way, we young fellows, with more strength than discretion, used to vie with each other who could wheel the heaviest load of stone and laugh well at the one who trembled most under his load. This, perhaps, was better than, as we say in Ireland, to be "schaming." Now for the result, which is, I think, the best proof of the utility of trenching. In due time the first crop that was planted in this trenched soil was Brussels Sprouts without the least manure; these reached the height of from 3 to 4 feet, well studded from bottom to top with fine firm sprouts. Such a remarkable growth I have not seen since, and proved, I think, in a marked manner the utility of deep soil. Doubtless the roots travelled to the full depth of the soil and spread in all directions, and these roots decaying would form a certain amount of food for future crops.

Some time after Raspberry canes were planted upon the same ground, and such moaster canes and heavy crops of fruit would almost astonish even Mr. Iggulden. In another part of the same plot Peas were grown to a great height with very heavy crops. The varieties I do not now remember, but they were staked with straight Hazel rods with fine side sprigs. The pods of Peas hanging between the stakes formed a very pretty sight from the ends of the long lines. Other vegetable crops were grown equally as successful with comparatively little manure. For some years after leaving the above-mentioned garden I was employed in others, but chiefly under glass, so had but little experience in the kitchen gardens.

About seventeen years ago I took charge of the gardens here, my first and only head place. One day the housekeeper came into the garden and said, "We never have Peas after July or August. They are always covered with mildew." This is a very old garden, the soil quite black with vegetable matter, and when I took charge of it the soil was about 12 inches deep, overlying poor hard marly soil. With the experience of my boyish days, and the tall Brussels Sprouts in mind, I commenced by deepening the soil a little every winter as time would afford, a trench being opened at one end of a piece of ground. A little of the surface soil with any other vegetable matter, such as leaves that had been used for hotbeds the previous year, was thrown into the trench, the hard bottom being well broken up and mixted with the black soil; when too hard for a strong steel fork the pickaxe was used. We were not at all so particular as many of your correspondents in bringing several inches of this soil to the surface, for when well mixed with the old vegetable soil it

gave it new life and was in a position to be made better. Winter after winter we trenched and retrenched part of the garden, until most of our soil is as good 3 feet down as upon the surface. The result was, Peas generally free from mildew and bearing until destroyed by frost; Ne Plus Ultra, still the best Pea I think, bearing crops until the blossom is destroyed by frost. Scarlet Runners, of which we never sow but one crop, bear well until November. All the Brassicas do equally well, especially Brussels sprouts and Cauliflowers. Potatoes, which are generally considered surface-rooting, delight in a deep well-drained soil. I have taken up from a single set of the Champion 18 lb. of good Potatoes. In 1883 single sets of the Reading Hero produced 15 lb. of sound Potatoes, which were exhibited in our local seed shop windows, and the smallest produce of any set in the whole plot would be over 10 lb. The roots of Potatoes I have found over 3 feet down.

Many object to deep loosening of the soil because the roots go down out of the reach of sun heat, but I think the secret of good fresh succulent vegetables, especially the Brassicas, is in having well-drained deeply worked cool soil. Who has not seen Cauliflowers in August with their leaves drooping in shallow soil and their roots longing to get out of the reach of the sun's rays and to where they could obtain moisture to lift their drooping heads?

Mr. Iggulden speaks of bonemeal and other manures applied liberally near the surface, but unfortunately we are not all blessed with employers with such long and well-filled purses as Mr. Iggulden, and have to resort to deep cultivation as a substitute for copious dressings of manure. I do not know a kitchen garden crop that is not benefited by deep cultivation of the soil. The roots of kernel and stone fruit trees should doubtless be kept as near the surface as possible, as the sun heat is of the greatest advantage to these if sufficient moisture is retained in the surface soil.—W. O., Fota Island, Cork.—*Journal of Horticulture.*

YARD MANURE AND WOOD ASHES.

I have been asked to state the comparative value of unleached wood ashes and barnyard manure for Apple, Peach, Pear, and Cherry trees, also in regard to composting the two. Barnyard manure varies to so great an extent that it is impossible to place a standard price upon it. What it may be worth depends upon the kind and condition of the animal, the nature of its food, the relative amount of litter mixed with it, and the amount of soluble materials removed by rain, &c. For this discussion I will take fresh horse dung as a standard, the horse having a mixed feed of one part Oats and three parts meadow hay, the dung being free from all stable litter. This dung contains 75 per cent of water, 2½ per cent of ash, and 0·10 of one per cent of nitrogen. A ton of such manure contains 12 lb. of nitrogen, worth 2 dollars 40 cents, and 50 lb. of ash, containing in addition to the lime, magnesia, sulphates, chlorides, &c., 11·6 lb. of potash, worth 77 cents, and 4·9 lb. of phosphoric acid, worth 61 cents, or a total value of 3 dollars 78 cents a ton, estimating these three materials at commercial rates. This calculation is made on the assumption that the phosphoric acid is all soluble in water, and that the nitrogen is as valuable for fruit trees as it is for field crops, both propositions somewhat doubtful. Wood ashes represent all the mineral elements of vegetable growth, and contain everything the farmer must give his crops except combined nitrogen. Wood ashes will vary in composition and value with the kind of wood and the part of the tree. I will take the ash of the body wood of the Beech tree as representing the average of wood ashes. A ton of such ashes contains 320 lb. of potash, worth 16 dollars, and 105 lb. of phosphoric acid (insoluble), worth 5 dollars 25 cents. Omitting all the other ash constituents, which have some value of themselves, the potash and phosphoric acid of a ton of such ashes are worth 21 dollars 25 cents, or nearly six times the value of a ton of fresh horse dung. For orchards I regard ashes as worth more than six times the value of barnyard manure, ton for ton. When barnyard manure is composted with wood ashes the coarse vegetable material and litter are rapidly broken down, and the manure is speedily fitted for use; but there is some loss of nitrogen in the form of ammonia, but there will be no loss of mineral matter if kept from leaching by water.—Dr. R. C. KEDZIE, Michigan Agricultural College, in the *New York Tribune.*

THE ELECTRIC LIGHT AND THE GROWTH OF PLANTS.

In conversation with Mr. Isaac Buchanan, one of the best known florists of New York, this subject came up, and he stated that his observation inclined him to believe that when plants were used for decorative purposes in rooms where the electric light was use instead of gas, they seemed to have all the health and vigour as if growing under the light of a conservatory. He furthermore said that he had long ago observed that on moonlight nights there was always a better development of the flowers of Camellias and Roses during the winter months than when there was no moonlight. Hence he inferred that light, no matter how obtained, was beneficial to the growth of plants. This opinion from such an authority as Mr. Buchanan, who is well known to have had nearly half a century's experience, and who has always been a close observer, is certainly worthy of great attention.

It is well known to all cultivators that the greater the amount of sunlight the greater will be the development of the flowers. We all know that in the dark days of December and January the growth of development of Rose buds, Carnations, &c., is less than half of what it is in the months of March and April, when the days have lengthened, and the increased sunlight gives nearly twice the amount of light. Few commercial florists have the means or time for such expensive experiments as would be necessary to determine whether the use of the electric light in forcing flowers and fruit in greenhouses during winter could be profitably employed. It is a matter of sufficient importance, it would seem, for the Agricultural Department at Washington to take hold of. For be it known that the gardening industry now in the forcing of vegetables, fruits, and particularly flowers, has millions [of dollars] of capital invested in it throughout the land, and gives employment to tens of thousands of men; and if Nature can be aided by this wonderful electric light it will be a leap forward that the discoverer might well be proud of.—PETER HENDERSON, in the *Scientific American.*

THE VEGETATION OF THIBET.

It is among these lower hills that the Camphor is usually grown, often to a colossal size, whilst another Cinnamomum, called Nan-moii by the Chinese, and which forms one of the most elegant and largest trees that can be seen, is only found in the alluvial plains of Setchuen at an elevation of about 1,700 feet. A single Rose, with rose-coloured flowers of a sweet scent, grows in the woods of Moupine; but the white flowering species with long shoots abounds there, as it does through all Central China. Among the numerous climbing shrubs I ought to mention one which is remarkable for having largely developed floral bracts, like our Bougainvillea, but white; also the Glycine, so common on the hills of the eastern provinces, but which is absent from the west. I have not seen here either the wild Camellia, with white flowers of moderate size, which is so abundant in the district of Kiangsi, where the best table oil to be had in the country is made from the fruits [seeds?]. As to the Chamærops, it may be seen prospering in Setchuen and Moupine up to an elevation of 3,400 feet, supporting with impunity the colds and snows of winter. This tree, the only representative of Palms in Central China, does not grow spontaneously farther north than the basin of the Yantze. In this region is found in a wild state and in abundance the Loquat of Japan and a Ligustrum. The Chinese make use of a Privet with persistent foliage, and of the Fraxinus sinensis, to raise their wax insect (Coccus pela). Pistacia sinensis, an Elæagnus edulis, as well as Citrus triptera, the only wild form of the genus, are found here. I ought not to forget to mention an Arundo, very near to our A. Donax, if not identical, which I have never seen but in

Setchuen, whilst the Phragmites abounds near all fresh-water courses. The trees cultivated in the province of Setchuen (which is considered to be the most beautiful and richest of the empire) and which need man's care to propagate them, are the same as those found in all Southern China; Mandarin Pear, Peach, Plum with red flesh, Dryandra Stillingia, immense Ficus lucida (near the pagodas), and above all, a numerous assortment of splendid Bamboos, which the inhabitants make use of in a vast number of ways. Besides the ordinary Tea, spread throughout one half of China, in the mountains of Moupine and Setchuen, a second species, called "White Tea," is cultivated; it is a shrub much grown, with slightly hairy leaves and of an elongated form.

The herbaceous flora of Moupine, and of the large mountains of Western China is proportionately less rich than the arborescent vegetation, but it is always more interesting there than in the north of the empire, where monotony is the striking characteristic of the vegetable kingdom. And if the northern flora comprehends a certain number of European genera and species, it is not so in Eastern Thibet, where these last are only represented by accidental Introductions. I should say that it is only a few years ago that the culture of Maize, Potatoes, and European Cabbages was introduced into these mountains, and without which it would only be possible for a small number of hunters to live. Another observation of interest is that when the old forests are destroyed by fire for the purposes of agriculture, the denuded land gives spontaneous birth to other vegetation, to a great quantity of Sinapis with oily seeds, from which the natives obtain two or three good harvests without any labour. As this species of Sinapis (which is largely cultivated by the Chinese throughout the empire) is not seen growing in the woods, one asks with astonishment, Whence and how has it orginated?

I should lengthen my letter without measure if I undertook to review the herbaceous plants of Moupine—those, more easy to prepare than the woody plants, are consequently better represented in my herbarium. I conclude by adding that in the valleys of Eastern Thibet I have counted fifty species of Ferns, and that in the high prairies of that region I have commonly found a large Rhubarb with palmate leaves, whilst the species with entire leaves is the only one that grows on the hills of Northern China and of Mongolia. The roots of these two medicinal plants are hunted after with avidity by the mountaineers, and constitutes an object of active commerce all over the empire.—ARMAND DAVID, in Franchet's "Plantæ Davidianæ."—*Gardeners' Chronicle.*

NITRATE OF SODA AS MANURE.

The committee of the Saltpetre Producers' Association on the West Coast of South America (Comité Salitrero, at Iquique, Chili) offers £1,000 in prizes for essays on the use of nitrate of soda as manure. Of this amount—

I. A prize of £500 will be awarded for the best popular essay, showing the importance of nitrate of soda as a manure, and the best mode of its employment.

The essay, in its theoretical part, is to treat of the effect of nitrate of soda on vegetation, as compared with other manures containing nitrogen, and should exhibit the present state of knowledge on this point. In its practical part the essay is to give directions for the use of nitrate of soda in the various conditions of plant culture. References and quotations and purely scientific explanations, if necessary, are to appear as notes. The essay may be written in English, German (italic characters), or French. The writing must be distinct, and on one side of the paper only. It is desired that the length of the essay may not exceed six sheets of printed octavo. Each manuscript is to be signed with a motto; the name and address of the author is to be given in a sealed envelope bearing the motto outside. The essays are to be sent on or before October 1, 1885, to any of the undermentioned judges.

II. A prize of £500 will be awarded for the best essay treating of the same subjects on the basis of new experimental researches made by the author himself. The essays must fulfil the conditions already mentioned. They may be sent to any of the judges on or before January 1, 1877. The committee of judges consists of the following agricultural chemists:—

Germany.—Professor Paul Wagner, Director of the Agricultural Station at Darmstadt.

England.—R. Warrington, Esq., Agricultural Laboratory, Rothamstead, St. Albans, Herts.

United States of America.—Vacant.

France.—Professor L. Grandeau, Director of the Agricultural Station, and Dean of the Faculty of Natural Philosophy at Nancy.

Belgium.—Professor Petermann, Director of the Royal Agricultural Station at Gembloux.

Holland.—Professor Adolf Mayer, Director of the Agricultural Station of the State at Wegeniogen.

Russia.—Professor L. Thoms, Director of the Agricultural Station at the Polytechnical Institution at Riga.

If none of the essays received should thoroughly satisfy the committee of judges, they are authorised to award inferior prizes of not less than £150 each. Any essay for which a prize is awarded becomes the absolute property of the Saltpetre Producers' Association at Iquique, which also reserves to itself the right of translation into other languages. (Signed) PROFESSOR PAUL WAGNER, Darmstadt, for the Comitè Solitrero, at Iquique. —*Gardeners' Chronicle.*

A NEW NATAL INDUSTRY.

Coffee was not a success but a sad failure in Natal. But it seems that the culture of tea promises to be more successful, judging from the following which appears in the *Colonies and India*:—

Sir,—During my late visit to Natal I was much interested by a new product for South Africa—*i.e.* Tea—the cultivation of which is being carried on somewhat extensively by Mr. J. L. Hulett, in the Umvoti district, Natal. This is no mere garden culture, for Mr. Hulett remarks that he compares his crop with an estimated yield per acre in India, where 640 lb. per acre is given as the yield in the tenth year. "My *picking* area has been this past season as follows:—About half an acre seven years old (imported hybrid plants), 4½ acres 1st year, 1881; 27 acres last year, 1882. According to the above estimate I should have manufactured:—

½ acre	... ...	... 240 lb.
4½ acres at 160 lb.	per acre	... 720 ,,
27 acres at 40 lb.	per acre	... 1,080 ,,
	or, total	... 2,040 lb.

Instead of which my yield for the season will reach 9,000 lb. of marketable tea." The foregoing remarks apply to the year 1883. When I left Natal (end of June, this year), Mr. Hulett had then over 70 acres of tea under cultivation.

The culture of land is not under any circumstance over 5*l.* per acre per annum: this includes weeding, manuring, priming, tools, &c., which, allowing 800 lb. of tea per acre (when five years old), will give 1½*d.* per lb. for the annual growth of the tea. The cost of picking comes to 2½*d.* per lb. of made tea; cost of rolling and drying, 2½*d.* This gives 6*d.* per lb. total cost of growing and manufacturing, exclusive of interest on capital outlay. Mr. Hulett further remarks:—"Had I possessed a rolling mill and drying furnace the cost would have been considerably lessened—say, picking and making, to 3*d.* per lb., or 4½*d.* in all. My opinion is that an enterprise is before the colony well adapted to the requirements of those possessing small capital, say from 500*l.* upwards: especially is this the case when ten or twelve can grow for a central factory." "Indeed," says Mr. Hulett, "I am quite prepared to purchase this leaf in the green state and give 3*d.* per lb. for the same direct from the tree until export becomes a necessity." The colony possesses thousands of acres that may yield an average of 800 lb. per acre, and Mr. Hulett is more and more convinced that tea growing in Natal is certain to succeed, and that it will prove a mine of wealth to the colony far beyond any gold mines that may be opened out inland. He kindly handed me some samples marked Pekoe 1 2 3, and I obtained a sample of rough tea from his local agent in Durban

These samples I brought home wrapped in paper in my portmanteau, and I submitted them to a tea taster to value, with the following results. (Copy herewith, which please publish at foot of this.) I trust the foregoing may be of interest to your readers, and may open the eyes of certain gentlemen who profess to see no value of England in the possession of her colonies.

I am, &c.,
MORTON GREEN.

[COPY.]

London, Sept. 1, 1884.

My Dear Sir,—I have put the samples of South African teas into liquor, and make them very decent value, as follows:—No. 1 sample, 1*s.* 5*d.*; No. 3 sample, 1*s.* 6*d.* to 1*s.* 7*d.*; No. 4 sample, 2*s.* 2*d.* to 2*s.* 3*d.*; and the very rough sample, 8*d.* to 9*d.*; these prices are without the duty. If the samples were not so small or broken in the leaf they would be of more value. I have also had the opinion of one of the oldest and most respectable brokers upon the samples, and he thinks with me. Tea from South Africa is a novelty, and if it can be produced without being so broken in the leaf, it would be worth more in the London market. I am, &c.,

To Morton Green, Esq. C. WIGHT.

[I may mention, with respect to the broken leaf complained of above, that Mr. Hulett informed me that he was much wanting in information in the rolling and drying of the leaf, which practice alone will perfect, and I think that Natal has reason to be proud of the perseverance and energy displayed by Mr. Hulett throughout, in working under the difficulties he has. I may add that tea is also under cultivation by several others in Natal, and that at the recent Industrial Exhibition (January, 1884) a gold medal was awarded for the best 10 lb. Further, I may state that I have placed a sample on view at the Royal Colonial Institute, Strand.—M. G.]

We cannot help thinking that in a colony which imports labour from India, the cost of production is under estimated.—ED.]

PLOUGHING MATCHES AT KAITY, S. INDIA.

Messrs. Massey & Company's "Indian Ryot Plough" was awarded the first place at the ploughing exhibition held at Kaity on Tuesday last. This plough has only just been brought out by them, in view to supply the wants of small landholders, and the poorest description of cattle. Its price is only RS. This is the first time that it has been exhibited to the public, and in every way it appeared to be well adapted to the requirements of the ryot. Messrs. Massey & Co. have made ploughs a *spécialité*, and the Judges were of opinion that if a competent person had worked the Indian Ryot plough, nothing in the Exhibition could have equalled it. That it did the best work could be seen at a glance—turning over much more earth than any of the others. The Burghers at first thought that English pattern ploughs worked well enough on a flat, and that they were not so well adapted for hill-side work; but the results on a steep slope in which three English pattern and one native plough competed, proved to them again the superiority of the Ryot plough. Messrs. Massey & Co.'s C. P. Patent Pipe plough for dry cultivation, a very light all-iron plough, which has taken all the prizes up to date, obtained, at this Exhibition, only third honors. This plough is adapted both for small and large cattle. The land selected for the matches had lain fallow for two or more years, was covered with grass, and was of ordinary quality. The first match was held on a partly flat or gently undulating ground, and the second a steep slope. The object the Collector had in view in bringing about these matches was to ascertain the sort of plough best suited to the land, and the cattle used for ploughing in this district, as well as to induce the ryots to improve their agricultural system, and thus introduce a better style of farming than what now prevails. The area of each plot ploughed, on the flat was a quarter of an area or 1,210 square yards. Time 1½ hour. When time was called the results of ploughing were as under:—

No. 1 plot	Burgher plough ...	Sq. yards 969
„ 2 do	Massey & Co.'s C. P. ...	... 644
No. 3 plot	Swedish plough shown by Mr. Creed	Sq. Yds. 999
„ 4 do	Small Swedish plough, by Oakes & Co.	499
„ 5 do	Avery's "American" plough ...	1,131
„ 6 do	Avery's Hindostan	481
„ 7 do	Messrs. Ransomes & Co.	649
„ 8 do	Massey & Co.'s "Indian Ryot plough"	814

The Judges then proceeded to inspect the several plots, awarding marks for "depth ploughed," "turn over" and general appearance." The depth of ploughing varied from 2½ to 3¾ inches, the Burgher and Avery's American plough doing the former, and the "Swedish" shown by Mr. Creed; Massey and Co.'s "Indian Ryot" and Ransomes & Co.'s sent up by the Saidapett farm, and worked by an experienced ploughman of the farm, doing the latter. For "turn over" Massey's "Indian Ryot" and Ransome's obtained an equal number of marks, as also for "general appearance." The Burghers secured for themselves the best pair of bullocks on the ground, while Avery's "Hindostan" had the worst pair. In fact the ploughmen entrusted with the working of "Avery's" two ploughs could not do justice to them. Messrs. Oakes & Co. brought out three ploughs, but two could not take part in the competition, being too heavy, as there was not a sufficiently strong pair of bullocks to drag them. The Swedish plough shown by Mr. J. L. Creed of Deva Sholah, was drawn by a large pair of Mysore bullocks, and did very fair work. The final order of merit was as follows:—

Massey & Co.'s Indian Ryot plough ...	... 1
Ransomes & Co.'s from Saidapett farm ...	... 2
Massey & Co.'s C. P. plough ..	... 3
Avery's Hindostan	... 4
Swedish plough shown by Mr. J. L. Creed	... 5
Oakes & Co.'s small Swedish plough ...	... 6
Badaga plough...	... 7
Avery's American...	... 8

—*Madras Mail.*

THE GROWTH OF CHICORY.

In these days, when we are bound to look carefully into our practice and see whether any and what alterations of cropping are likely to be profitable, any reliable information and advice as to the cultivation of special crops should be gratefully welcomed, and received with careful consideration. It is for these reasons that we desire to call attention to a lecture by Mr Foster, of York, "On the Growth of Chicory," read before the Derwent District Agricultural Club at Stamford Bridge on Feb. 25. It opened with the statement that in the very district of the club hundreds of acres were formerly occupied with this crop, which not only benefited the growers, but furnished a large amount of employment for the labourers. The subject was treated under three heads—(1) Cultivation and Growth. (2) Duties and their Injurious Effect. (3) Remedies Suggested. Mr Foster controverted the opinion too generally held by owners and agents, that chicory is exhausting—declaring emphatically that the growth of chicory, instead of deteriorating the land, greatly stimulates and improves it. Clean cultivation and the application of suitable manures are essential elements of success. In illustration of this, the evidence of one of the largest growers in England was cited to the effect that he had grown fourteen consecutive crops, and after that a good crop of corn. The crop is sown about the middle of May, 2½ lb. of seed being drilled to the acre. The crop, which resembles white carrots in the growth of root, is taken up from Oct. 10 to end of November. Cost of this business and washing is about £4 an acre. The next process is slicing by a special machine, afterwards drying on a kiln. During this process the exciseman appears, and gives no end of trouble. After being dried it is weighed into the store, locked and sealed, and cannot be inspected or sold without due notice to the officer. Green chicory is reduced by drying to one-fourth of its original weight. About two tons per acre of the dried crop is a fair yield, worth £8 to £10 a ton. The chicory merchant roasts it in revolving cylinders and converts it into nibs, in which state it is sold to the grocer.

So much for cultivation and manufacture. The first duty of 3s. a cwt. on dried chicory was imposed in 1860, at the same time as a duty of 6s. a cwt. on foreign chicory. This differential duty in favour of the home grown allowed of growth being profitably continued; but steadily the excise increased, until in 1872, after the duties on chicory and coffee had been largely reduced by Mr. Lowe, the excise was 12s. 1d., and the duty 13s. 3d. At that time the import was 101,504 cwt., and the home produce 11,168 cwt. In 1884 the former has reached 119,355, and the latter declined to 2,952 cwt. At the present time the growth of chicory, as an agricultural interest, is almost extinct. Previous to 1860—*i.e.*, about 1852—there were fully 1,000 acres under cultivation in the immediate neighbourhood of York. No doubt coffee is not consumed so largely per head now as formerly, tea being more commonly used. Mr Foster, after estimating the acreage near York in 1867 at about 515 acres, states that last year the whole of the English crop only occupied about 74 acres. Put in another way, he says: "Prior to 1860, for every ton we grew at home the foreigner (Belgians) grew us one abroad; prior to 1867, for every ton we grew at home the foreigner grew us four abroad; prior to 1884, for every ton we grew at home the foreigner grew us 40½ tons abroad." By way of restoring the home trade, Mr. Foster suggests a return to a differential duty in our favour of from 3s. to 5s. ton, and a cheaper, simpler, and less annoying system of collection. One argument for reduction of duty is that it is so very large in proportion to actual value. The duty on coffee, or rather the Customs, are only 14s. a cwt., although the value of the article is three times greater. As regards collection, the lecturer suggests that it should be after the article reaches the manufacturer's hands, as in the case of beer, or by a label duty. Mr. Foster declared his intention of bringing the matter before the Chancellor of the Exchequer. If a differential duty was objected to on free-trade principles, he would advocate the immediate and total abolition of the chicory duty—a small matter, as the total revenue from all sources only reached £75,000 last year; as he believes that, with entire freedom from restrictions and interference in drying and manufacture, with a fair field and no favour, we could, as we have done in the past, hold our own successfully against all foreign competition.—*Field.*

RENOVATING OLD TREES.

Trees are like human beings; after they reach a certain age or state of debility, no restorative measures that one can employ will produce any lasting improvement. But in the case of trees that are still comparatively young, and which may be suffering from neglect of some kind, and are not deficient in vitality, renovating measures are often attended with most satisfactory results. It takes time, however, and patience must be exercised. What has been going wrong, may be for years, will require a proportionately long period to be put right again, but the progress of improvement will be more rapid every year. This is owing to the peculiarities of tree growth. Improvement always, of course, takes the shape of better growth, healthy foliage, and stronger wood. These in turn deposit fresh layers of tissue, which promote a more active circulation of the juices every season, the effects of which are observable in the more rapid distention of the trunk and limbs, and a proportionate increase in the roots, till, in time, the tree grows out of its debility and recovers. Old fruit trees are oftener operated upon in this way than other subjects, and there are few gardeners who are not familiar with examples of old or feeble vines or peaches, &c., that have, so to speak, been made to renew their youth in the course of a few years. Feeble-growing and unhealthy trees are, as a rule, the result of starvation, bad soil, or unfavourable conditions of the atmosphere, climatic or otherwise. When a tree dies from old age, the signs are plain enough, and very little can be done to help it, except taking great care of the scant foliage it puts forth each year, and encouraging young growth by every means to sustain the flickering vitality; but in other cases the same signs are observable in young trees, the causes of which may be found and removed. One of the surest signs of debility is the pushing of adventitious growths from the trunk and main branches, and the dying off year by year of the twiggy terminal shoots. The sap does not circulate freely to the extremities, but chiefly about the trunk, putting out a feeble growth on those parts, which grow stronger the nearer they approach the root. Old laurels often afford very good examples of this. When the tree is healthy, the top is luxuriant; when it is weak or old, the top dies, or makes little or no growth, and small shoots sprout out all over the trunk. Very often, when such bushes are cut over, they push from the base and do well, and if aided by good soil put to the roots, the result will be all the more satisfactory. In fact, renovating measures may be said to consist in the judicious removal of the feeble decaying tops and branches, and encouraging fresh root action. The trees should be pruned rather late in the spring, when growth is about commencing, and only the really diseased or dead portions should be cut away, unless the subject be one that would be better cut down altogether. This having been done, the roots should be examined, and, if there be reason to suppose that water stagnates about them, the site should be drained thoroughly. In such a case, that of itself will effect a cure. We remember once a case of several young trees that were mysteriously dying off year after year at the extremities of their shoots, a wet soil not being suspected as the cause, because the whole ground had been drained years before. The accidental digging of a pit near where they grew, however, revealed the water standing within fifteen inches of the surface, owing to the main drain having been choked up. We need not say the obstruction was removed, and the soil and trees both presented a better appearance afterwards. But it is not so often that want of drainage is the cause of trees dying. In thin indifferent soils the cause is simply want of sufficient nourishment, and drought—both bad in themselves; and the cure is a good layer of fresh soil, common manure, leaf mould, and the like laid over the roots, and thorough watering during the summer, whenever the ground is the least dry. Only those acquainted with such matters know how dry the soil becomes where the roots of trees abound, and it takes much water to soak it afterwards. The fresh soil and the water will work wonders. The effects will not be very apparent the first season, unless it be in the production of numerous buds and small growths from the older wood; but the next year and years following the progress will be very marked, till the tree quite fills up with young healthy growth again. This is observable in the case of all evergreens, but especially in yews, hollies, and rhododendrons, &c. Conifers, too, reciprocate such generous treatment, but they must not be allowed to go too far, as it would then be almost as well to plant fresh trees.—*Field.*

CHINESE VEGETATION.

[The following extracts are taken from a letter of the Abbé David prefixed to Mr. Franchet's enumeration of the plants collected by that adventurous traveller, recently published in the *Nouvelles Archives du Museum*:—]

From a naturalist's point of view I divide the Chinese empire into three large regions—1st, Northern China, extending from the Yellow River, or Hoang-ho, to the confines of Mantchouria; 2nd, all Eastern Mongolia, which adjoins the Great Wall; 3rd, all that region, generally mountainous, which forms the South of China, including the immense basin of the Blue River or Yangtsekiang.

NORTHERN AND EASTERN CHINA.

The two first regions resemble each other greatly in vegetable and animal productions and in climate. The last is characterised—1st, by great dryness, interrupted in summer by occasional storms; the rare showers of rain or snow which take place in the rest of the year are for the most part insignificant, and dews are not seen until about the commencement of July after the first rains; 2nd, by an unusually clear sky, with north winds, as disagreeable as they are frequent; 3rd, by the regularity of the seasons—the cold of winter and the heat of summer being rarely broken by abrupt alterations of temperature; 4th, by a long very hot summer, and by a rigorous winter. At Pekin the severe cold commences suddenly in November, but the waters of the rivers and sea are not frozen over

until December, to thaw in March. Each summer the thermometor attains, and sometimes exceeds, 40° C. (104° Fahr.) in the shade, while the severest cold of winter varies between—8° C. (17° Fahr.) and—12° C. (10° F.), descending exceptionally to—20° C. (—4° Fahr.); but in Mongolia a cold of—30° C. (22° below zero Fahr.) is not rare.

This peculiarity which Northern China shows of being subject to regular alternations of hot summers and rigorous winters makes it impossible for a perennial or ligneous plant from a cold country to live there, although species of tropical annuals prosper there, and are cultivated far north. For the same reason Bamboos are not found in a wild state higher than the Hoang-ho, although they abound in all the mountains of the South beyond Tsing-ling. On the other hand, Rice, Sesamum, Cotton, Sweet Potato, and a number of the Cucurbitaceæ, are cultivated with success as far as the confines of Mantchouria. Again, although China has many species of wild Vines, the two or three varieties which are cultivated in the neighbourhood of Pekin (introduced, no doubt) only live there because the people are careful in winter to cover them entirely with earth.

It appears that several centuries ago the Chinese destroyed all the forests, perhaps to satisfy their agricultural and industrial requirements—perhaps, as I believe, to destroy the haunts of the great and formidable animals (tiger and leopard) near which man could not live in security, especially if he kept but few cattle, as is the case here. It is among the reputedly inaccessible mountains that remnants of the ancient forests are found, and generally the country is without spontaneous shrubby vegetation, even on the hills. As to the plains, almost every part is so devoted to agriculture, that the indigenous plants have almost completely disappeared: especially so, as the Chinese have no meadows, and as they are careful in winter to hoe up all the wild plants with their roots to supply their kitchen fires!

The vegetation of the northern region is poor and little varied, especially on the Mongolian plateaux, where the meagre plots of grasses, widely scattered, alternate with immense plots formed by Artemisias, Iris, Glycyrrhiza, studded here and there with bushes of Caragana, Ephedra, Clematis, and Roses. Inside the Great Wall the ligneous wild vegetation which has best resisted the vandalism of the Chinese, and which gives to the flora of the country its peculiar appearance, belong to the generas Zizyphus, Vitex, Lycium, Lespedeza, Rhamnus, Clematis, Euonymus, Celastrus, Ailantus, Morus, Ulmus, Plauera, Salix, Populus, Biota, Juniperus, and Pinus. Besides, on the mountains, there are the Quercus, Carpinus, Betula, Tilia, Juglans, Corylus, Corylopsis, Xanthoceras, Koelreuteria, Larix, Abies, Vitis, Lonicera, Fraxinus, Syringa, Ligustrum, Philadelphus, many Spiræas and Roses, Cratægus, Sorbus, Sambucus, &c. There is no Hedera (Ivy) in the north, but Cornus and Aralia are found there.

The trees which are commonly planted to shade the habitations are the Willow, Poplar, and Ailantus—often the Sophora and Cedrela, and as a luxury the Salisburia, but these last are imported species, like the Kaki, which is cultivated on a large scale on the hills. However, it is only in the mountains of Pekin that I have seen in a wild state the black fruited Diospyros, while it is only in the South that I have found the D. Kaki with little yellow fruits growing spontaneously. As to the beautiful Pinus Bungeana, which ornaments the courts of the temple of Pekin, I have not been able to discover where it exists in a spontaneous state. Of the three or four Poplars of China the most remarkable is that which I have pointed out before under the native name of Ta-yang. To its height and elegant appearance it joins the advantage of furnishing one of the most esteemed woods of the country. The Chinese cultivate fruit trees but little, and that badly; however, they possess nearly all those genera that we have in the West. On this subject note that we find in the Chinese mountains, growing in their primitive and spontaneous state, the Chestnut, Walnut, Apricot, Peach, and Cherry, but not the true Plum. Can this old land of the extreme East be the principal, or even the only cradle of these useful plants now spread through all the countries of temperate climate?

The little taste of the Chinese for fruits offers an explanation why they have neglected to domesticate the Strawberries, as also numerous species of Gooseberries and Raspberries, the existence of which I have proved in all their large western mountains. In the region of the Tsing-ling the productions of the North mix with those of the South. There, Paulownia, Catalpa, Sterculia, Cedrela, Melia, Rhododendrons, &., begin to grow spontaneously; but the greater part of the flora is Northern rather than Southern, and it seems to me to contain a good proportion of species peculiar to the country.

The southern provinces, situate to the south of the Yangtse, have a sub-tropical climate, rain is frequent there all the year, less, however, in winter than in summer. The vegetation, also, is much more abundant than in the North, without being at all varied. By Kiangsi the country is verdant and the hills are covered with large herbs, with a number of bushes interspersed, and with some trees or shrubs peculiar to the South: Vitex, Pachyrhizus trilobus, Smilax, Liquidambar, Fortunia, Cunuinghamia, the small Castanea chinensis, Rhus semialata, Chamærops Fortunei, &c. It seems that the flora of this region contrasts greatly with that of Japan.—*Gardeners' Chronicle.*

RHEEA FIBRE CULTURE IN SOUTH INDIA

To the Editor, "The Field."

SIR,—It may interest the readers of your paper to learn that a considerable impetus has taken place with regard to the above since I wrote the article which appeared in *The Field* of Feb. 17 of last year, and at the present time great attention is being devoted to fibre culture both in the Nilgiri and Wynaad districts, to which my article specially referred. In all possibility, provided favourable reports still come to hand, several private ventures will shortly be launched with a view to making fibre culture one of the future paying industries of South India, the extent of land available for cultivation in these districts being practically unlimited, and the country favoured with a constant and abundant labour supply, the cheapness of which is unequalled in any other part of the world. Hitherto the principal, if only obstacle in the way of success, has been the want of a machine calculated to decorticate the fibre successfully, and with the least possible waste; and yet at the same time so simply constructed as to be easily understood and readily manipulated by native labourers, and various machines have been projected from time to time, some even being of such an elaborate character as to render the use of chemicals necessary in order to dispose of superfluous matter, and to finish off the fibre by giving it a bleached appearance. It is almost needless for me to observe that, apart from these machines proving useless in practice, even with skilled European labour, anything of an intricate or puzzling nature proves worse than useless in the hands of a Hindoo agricultural labourer; therefore, the simpler the construction of the machine, the more likely to be its permanent value. Such a machine came under my notice about twelve months ago; its success I predicted from the first, and in consequence did not hesitate to recommend it to several gentlemen interested in rheea culture, especially after examining its work, including the specimens exhibited at the greater Textile Fabrics Exhibition held at the Royal Agricultural Hall, Islington, in August and September last. The machine I refer to is known as the Death & Ellwood's, and is the property of the General Fibre Company, Limited, 141, Fenchurch-street, E.C. It was, unfortunately, too late to be shown at the Calcutta International Exhibition; but recently, at a competition held at the same place under the auspices of Government, this machine proved its superiority over all others, and has received the full Government reward of R2,000. This reward, I may mention, has been offered from a time dating many years back, the Indian Government being fully cognisant of the value of a machine for fibre-cleaning; and still later intelligence has arrived that this machine has been awarded the gold medal at an exhibition held in Mauritius.

It is clear from the above that a revolution in fibre matters will sooner or later take place; by this I mean that many of the inferior products now in the market, and at present imported for want of better, containing as they do from 15 to 40 per cent of useless matter, will be completely ousted by those which are almost perfectly free of foreign substances; and there remains little, if any, doubt that India will, in the immediate future, largely supply the principal markets of the world

with rheea the most valuable, to the exclusion of many of those now imported. The first in the field in new industries usually proves the most successful, and in Southern India the lead has been taken by the Glenrock Company, which, although originally a mining company, has now turned its attention from gold prospecting to a more certain method of earning dividends for its shareholders. On this Company's property a considerable acreage of rheea has already been placed under cultivation, and latest advices from the district state that the growth is simply astonishing everybody. Taking into consideration that the forcing Wynaad climate is admirably adapted to the growth of rheea, this report is not surprising; and, now that a machine worthy of the name has been invented and passed the necessary tests satisfactorily, there remains no reason why rheea culture should not prove the success that has been anticipated in the past. I must here reiterate the caution urged in my former paper, namely, that planting it at a low elevation will, unless under peculiar circumstances, such as shade and irrigation, be found a mistake. An elevation of from 3,000 ft. to 5,000 ft. above sea level will be the most suitable. Various estimates have from time to time been submitted by experts interested in rheea culture, who, more or less, have been considered competent to judge results from experimental cultivation, and I find their estimates have ranged from 8 cwt. to 10 cwt. per acre per annum up to as high as 4 tons. It will be seen from this that some have either been over sanguine or have miscalculated in a most peculiar manner. My opinion always has been, and I see no reason to alter it, that 17 cwt. per acre per annum should be the outturn for the first year following that in which it was planted—*i.e.*, provided the land has been thoroughly well cleared and the soil well loosened before planting. Nothing is likely to retard the growth and proper development of quick-growing, soft-wooden plants, to which class the rheea plant belongs, than an unbroken virgin soil; and if the plants are merely dibbled out in small pits or holes, not more than 8 cwt. per acre per annum can possibly be expected; in all probability even a lesser return would be the result. But under liberal cultivation, such as planting strong crowns in well-trenched rows and a fair supply of manure, the outturn per acre which I have mentioned should be at least obtained, increasing annually as the plants, which are of a perennial nature, mature. The value of manure in rheea culture cannot be over estimated, its use being as necessary as in the culture of the hemp or flax, it being fully recognised by cultivators of these products that fibre-yielding plants exhaust the soil in which they are cultivated much sooner than any other class of crop.

With regard to the districts I have brought under notice since penning my former article, I understand that the Indian Government has sanctioned the extension of a railway from the Mysore country to the market town of Goodaloor, which may be regarded as being almost centrally situated in the Wynaad district. This convenience, when carried out, together with the Metapolleim terminus on the Coimbatore side of the Nilgiris, should be the source by which to obtain abundance of manurial composts, including fish, bones, poonac, &c., at strictly moderate prices. To capitalists and others in search of new fields in which to place both their money and their labour, the districts and industry I have referred to afford ample scope for the development of their energy, and to those possessing sporting proclivities a more favourable part it would be difficult to select. Since the local game laws came into force all kinds of game have been on the increase, and I trust I am not diverging too far from the subject when I mention that the following are of common occurrence, and on the higher ranges of the Nilgiris may be obtained: Snipe, woodcock, spur fowl, quail, jungle fowl, hares, Muntjac deer, sambur, ibex, wildboar, &c., whilst in the Wynaad, or along the forests on the Mysore road, can be found in addition spotted deer, bison, bear, leopard, locally termed "cheetah," and occasionally tiger; the smaller game including partridge, peafowl, wild duck, &c. Land is purchasable as reasonably as it is possible to obtain good land anywhere, and often a good tract, containing an area under cultivation, with the usual estate buildings, can be secured at a very reasonable cost.—W. G. KEMP.

SQUIRRELS AND LIME TREES.—On the morning of the 22nd inst. my brother and I watched a squirrel busily employed in stripping the bark off some long shoots of a lime tree close to our windows. He filled his mouth with a large quantity (of course for his nest) and made off. Seeing that the boughs were completely peeled in places, we jumped to the conclusion that he was doing immense damage. On closer inspection, however, of the boughs with a ladder we found that all the boughs peeled were already quite dead. I should like to know if any of your readers have ever found living boughs peeled. In the one case he would be doing no harm, but in the other despite his beauty, he would have to be sentenced to death. —GILBERT G. PLANE.—*Field.*

THE IMPORTS OF CAOUTCHOUC.—Messrs. Hocht, Levis & Kahn, in their caoutchouc report for 1884, state that the year was "one of, if not the most remarkable in the annals of the indiarubber trade." The price of the leading sort, fine Pará, furnished by Hevea brasiliensis, gradually declined, with few temporary reactions, from 4s. on January 5 to 2s. in July, thus showing a fall of 50 per cent in a little over six months. The reason of the decline is said to be due to accumulated large stocks, at times pressing on the market; to a decrease of consumption in the United States of America, one of the largest consumers of rubber; and to the "inevitable reaction from the artificially high and unwarranted rates at which a reckless and desperate speculation had succeeded in keeping them for some years." The total exports from Pará to all ports are estimated at 10,600 tons, against 10,130 tons in 1883. The exports into London and Liverpool during the year were 4,610 tons against 4,637 tons in 1883, showing a decrease of 27 tons. Of the total exports from Pará the United States have taken about 5,900 tons direct from Pará, besides which they have also taken moderate quantities from Europe. The imports into Liverpool of Ceará scrap rubber from Manihot Glaziovii amounted to 80 tons—a slight increase on the imports of the previous year. Of Central American rubber (Castilloa elastica) the imports were 35 tons, and of the African kinds, from species of Landolphia, the imports were 1,650 tons. The imports into London were as follows:—Assam and Rangoon, 250 tons; Borneo, 390 tons; Penang and Java, 90 tons; Mozambique, 860 tons; Madagascar, 135 tons; and of Central American, West Indian, Columbian, Carthagena and Guayaquil, 235 tons collectively.—*Gardeners' Chronicle.*

AS OTHER INSTANCES OF HOW LITTLE EUROPEANS IN THE EAST know beyond their daily routine, I may mention that it is only quite recently that the ocellated argus pheasant has been known to exist in Tonquin, yet Europeans have resided there for over two hundred years. Not six Europeans in Calcutta know that rhinoceroses and tigers are shot occasionally within fifteen to twenty miles of the town, leopards within five miles; in fact, anyone would look upon it as a "fine joke" indeed if told that these animals were to be found within one hundred miles even. I could mention twenty traces or more in the East of which European "residents" know absolutely nothing. Take the musk trade between Bootan and Calcutta, ditto Nepal, ditto Cashmere; how many Europeans come in contact with the Cabul merchants that march the scores of big elephants from Siam through Burmah to India? How many "residents" (with one exception) know of the enormous trade that these poachers carry on in the north-west of India? Notwithstanding the severe restrictions that were placed upon snaring monáls, hill argus, &c., notwithstanding the actual prohibition of trapping or destroying for five years, yet these birds arrive in skin by thousands—aye, tens of thousands—as Mincing-lane and the Paris houses can testify. Where is the "resident" who can tell me from whence come the thousands of blue king-fisher skins that leave Calcutta monthly for China? or give any information of the quantities of baskets of rhinoceros' horns that are brought down from Upper Burmah and pass through Rangoon to go to China? How many officials know of the enormous quantities of live guinea fowls that go to Singapore and China monthly from India? I could go on in this manner indefinitely; I am, however, afraid to occupy too much of your valuable space. The average number of dwarf elephants procurable being only about eight or ten per annum, goes far to prove that they are not by any means plentiful in the island.—CHINGAREE.—*Field.*

TEA MANURES.

In my article (see page 841) on the above, I specially referred to the high character which Ceylon tea had hitherto maintained in the London market on account of its fine flavor and rich dark coloured liquor, and I strongly recommended planters not to sacrifice *quality* for *quantity* especially as the tea industry was comparatively new in Ceylon and great attention should therefore be paid to keeping up the good name already obtained.

In the weekly circular received this morning from Messrs. Elliot Lack & Porter I notice that this question of quality is also alluded to in their remarks upon Ceylon tea, and I think you would do well to bring the matter prominently before the notice of planters. I understand that the writer was formerly for several years practically engaged in Assam tea manufacture, and on his way home spent some time in Ceylon, more particularly in Dimbula, where he made the acquaintance of several planters, so that you may consider his remarks well entitled to careful consideration. JOHN HUGHES, F.C.S.

(From *Elliot Lock & Porter's Indian Tea Memorandum.*)
8, Great Tower St., E. C., 2nd April 1885.

Owing to the approaching Easter holidays public auctions for the week terminated yesterday with the small total of 12,020 packages of which 437 failed to find buyers in the room. The market has continued firm and competition good, grades below 1s being in special demand and pekoes 1s 6d and upwards with attractive cup point are eagerly competed, for, rates showing occasional improvement. Indications are strong of the rapid closing of the season and consequent scarcity in the future of the more desirable parcels. The following prices have been realized.

ASSAMS.—Moahund, pekoe 2s, broken pekoe 1s 9d, pekoe souchong 1s 1d, broken 10¼d. Jokai Co. Jameerah Derry pekoe 1s 11¾d, pekoe souchong 11½d to 10¼d.

CEYLON TEAS.—593 packages sold consisting of a varied assortment; offerings from some few estates showed very desirable quality and were strongly competed for, prices ruling high, whilst the moderate and poorer qualities attracted less attention.

We think, we perceive indications that some managers are falling into the fatal mistake of attempting to produce excessive outturns, and as generally follows, sacrificing, to some extent, quality. Hitherto Ceylon growths have been especially attractive, as they supply a class of tea, which has of late years been scarce, full dark liquors with rich flavour suitable for drinking unmixed with other kinds: (avoiding the hard pungency of Assams and somewhat light pungent character which has been common during the last few years amongst Darjeelings) Quality must be maintained or prices will probably soon fall to a level of the ordinary Indian, China, or Java sorts. The produce of estates being now generally small, we think managers would do well to increase as far as possible the size of the breaks, sacrificing the numerous assortments for lots of less than 10 packages seldom if ever bring their full value, and assortment, especially of the lower grades, except the elimination of dust and red fannings is comparatively useless.

The following prices have been obtained this week:—

Dewalakande, pek. 1s 7d, bro. pek. 2s 3¾d, pek. sou. 1s 1½d.
Blackstone, pek. 2s 1¾d, bro. pek. 2s 7½d, sou. 1s 5d, bro. 1s 2d, dust 1s.
Indurana, pek. 1s 4½d, bro. pek. 2s 3½d to 1s 10½d, bro. pek. sou. 10¾d, dust 7½d.
Dunedin, pek. 1s 4d, bro. pek. 1s 9¼d, pek. sou. 1s 0¾d, bro. 10¾d, dust 7½d.
Ceylon Company Meddecombra, pek. 10½d, bro. pek. 11¼d.
" Becherton, pek. 1s 0½d, bro. pek. 1s 2d.
" Hepe, pek. 11½d, bro. pek. 1s 1d to 1s 5d.
" Koladenia, pek. 10¾d, bro. pek. 1s 0¼d, pek. sou. 10½d.
K A W, pek. 1s 4½d, bro. pek. 1s 10½d, pek. sou. 1s, bro. 7½d.
Blackwater, pek. 1s 2d, bro. pek. 1s 7d, pek. sou. 11½d, bro. tea 9½d, congou 9¾d, and red leaf 8¼d.

"THE PRINCE OF PALMS."*

We have too long delayed to notice this little compilation, a specimen of elegantly printed, bound and even illustrated volumes which are becoming common in this age of trade, enterprize and ingenuity. No doubt many of our readers know the establishment of Messrs. Treloar & Sons in Ludgate Hill, and have, like the writer, stood in admiration, before the display of mats, and other coir manufactures with their artistic workings and mottoes. We obtain in the pages before us a good deal of information respecting Messrs. Treloar's manufacture of coconut fibre with illustrations of their Pompeiian mats—"Salve," "Cave canem," &c.,—and an engraving of their "Mat and Matting Factory in Southwark." Our readers will guess from this that the "Prince of Palms" is a trade productious but injustice will be done to Mr. W. P. Treloar if it is supposed to be nothing more. In fact this gentleman's family have some right to take an interest in the aforesaid "Prince"—the Coconut—since the first introduction of coir as a material for manufactures in England was, we are told, "about 50 years ago when Capt. Wildey who had long resided in Ceylon, brought it under the notice of Mr. Thomas Treloar, the father of the firm of Treloar & Sons. In compiling a notice of the "Prince of Palms," Mr. W. P. Treloar would therefore seem to have been undertaking a labour of love and he has certainly spared no expense to make his brochure attractive, the coloured frontispiece, entitled "Inflorescence of the Coconut Palm (*cocos nucifera*) and Ripe Nuts," from an oil painting in the possession of Messrs. Treloar & Sons, being very well executed so far as the rich flower and young nuts are concerned, though the green leaves in the background are more like those of the areca than the coco palm. It seems that the present work is based upon a pamphlet on the same subject published by Mr. Treloar, senior, some forty years ago, and engravings from several works, including Tennent's Ceylon, have been made use of. These engravings are on the whole very well executed —the best being full pages, on 'Husking the Cocoanuts,' 'Climbing the Trees' (where, however, the proper mode of climbing is not shown), 'Bundling the Yarn,' 'Burying the Husks,' 'Coconut Trees in Tahiti and Fiji,' and the fine avenue of palms in the Rio Gardens; 'a Coconut Plantation in Ceylon,' is, we think taken from our own volume "Ceylon in 1884.' There is not much information in the 40 pages of letterpress that would be novel or interesting to Ceylon readers, save what we have already referred to about the beginnings of English manufactures of coir and the enormous consumption of late years in Europe, and especially in England, of the coconut itself. We may well quote what is said on this point:—

Coconuts have become an ordinary article of commerce in markets and many fruiterers' shops, but still the outer husks and shells are comparatively out of sight. Probably many people may still fancy that they are not brought here with the nuts in any considerable quantity, nor would the majority even of Londoners easily estimate the enormous consumption of the nut itself. A reference to the "inward" shipping lists, or a visit to Monument Yard on Fish Street Hill, where the catalogues of the foreign fruit auctions may be seen, would disclose the fact that hundreds and thousands of tons of these nuts, enveloped in the outer shell, have for some years past been brought here as "dunnage" by homeward bound ships. They are sold in big lots, and the buyers have to clear them from the docks. For sometime the outer shell was of little value, and was often split from the nut to be

* By W. P. Treloar: London, Sampson Low & Co.

sold as fuel, and for lighting and rousing fires. The nuts, too, offered a problem even after they were cracked; but perhaps we learned something from the natives of Ceylon and other who grate the nut as an ingredient of "Curry" and of pastry; at all events, there is now an immense consumption of the raw nut as an article for confectionery in a hundred forms, or for mingling with other ingredients in the production of elegant and delicate additions to the dessert.

If anyone would know where a great many of the cocoa-nuts go after they are hoisted out of the ship's hold in the docks, it might be well to take a walk into the Jewish quarter of London—about Aldgate, and so to Duke's Place, and what was once the orange market. They will see cellars full of cocoa-nuts, or their husks; the latter being periodically cleared out, not for fuel, but to form material for a very useful industry by which the stiff, elastic fibre of the inner portion of the shell is retted for the purpose of making brushes for stable and other uses. Such refuse as remains is found suitable for certain garden purposes, especially as a mulching for ferns, rhododendrons, and other plants.

But the consumption of cocoa-nuts here falls into insignificance when compared with the quantities used for food in the countries of their growth, and with the incalculable numbers which are taken from the groves of Polynesia, the Society Islands, and from Ceylon, for making coconut oil, a product from which we receive, not only oil, but stearine, after the oil has reached this country.

After this we are reminded that the first cocoanut ever produced in Europe, was by Mr. Smith of Isleworth,—who had charge of the Duke of Northumberland's estate at Sion, near London,—in December 1863. Of course this was on a tree grown in a conservatory. Under the heading of "Round the World and Home Again," Mr. Treloar gives a good deal of information, some of which we shall copy into our own fuller compilation on the Coco palm. Referring to the other palms, he has much to say about the Date:—

The Date Palm, is the tree which most immediately occurs to the imagination when "Palms" are mentioned. The branches and leaves of this palm have sacred associations. They are symbolical of triumph or rejoicing, and have borne an important part in great manifestations. This is noticed by Dr. Berthold Seeman in his learned and interesting "History of the Palms," and he quotes the charming lines from Goethe:—

"In Rome upon Palm Sundays
They bear true palms;
The cardinals how reverently,
And sing old psalms:
Elsewhere, those psalms are sung
'Mid olive branches:
The holly branch supplies their place
Among the avalanches:
More northern climes must be content
With the sad willow."

Dr. Seeman reminds us that the *Salix Caprea*, a goat willow, goes by the name of palm in Northern Germany.

Rosaliud, in Skakspeare's "As You Like It," says—"Look here what I found on a Palm tree"; and the notion of a palm tree in the Forest of Arden, has puzzled commentators who did not know that in Northamptonshire and elsewhere the goat willow is called the palm probably from its having been used for church decorations on Palm Sunday, when its graceful yellow blossoms, appearing in early Spring, made it particularly suitable for the purpose.

But it is in respect of Coir Fibre manufacture that Mr. Treloar is particularly at home, and the following reference is of interest sufficient to warrant its reproduction here:—

As early as 1832, Captain Wildey had commenced the trade. In 1836 he opened a cocoa-nut fibre depôt in Agar Street, Strand, and there the firm really commenced operations. In 1839, Captain Robert Logan, who was then a partner, took out a patent for the manufacture of the fibre into various fabrics; and machinery and treatment of the fibre so rapidly improved that cocoa-nut matting, of our manufacture, was laid in St. George's Hall, Windsor, previous to the ceremony of christening the Prince of Wales, in January, 1842, the *Times* of the 26th January that year recording the fact that "the floor was covered first with a matting made of the husk of the cocoa-nut." The increase in manufactures from this fibre was more rapid after the Exhibition of 1851, and by the time that the second Exhibition was opened in 1862, had grown into an important industry, though it had not been fully developed.

Some of the mottoes worked into mats, as ordered by customers, are very curious, for instance, "Use me" and "Use me well" are very appropriate on a door mat; the "Cave Canem" mat is an exact copy of an old pavement found at Pompeii; the fac-simile may be seen in the Crystal Palace at the entrance to the Pompeiian Court.

It is unnecessary to follow the remarkable increase in the demand in successive years, or to explain the cause of fluctuations in the supply of raw material (coir fibre and yarn) but the following table will indicate the general increase in the importations of those materials from 1866 to 1882; the manufacture of mats and matting having been largely augmented, while other uses to which the material was adapted were also multiplied. We should mention that these particulars have been supplied to us by our friend, Mr. J. A. Noble, who has for many years been connected with the importation of coir to this country.

The table referred to will be given in our volume, and we would ask Mr. Treloar and other popular writers on this palm and its products whether they could not follow our example in dropping the final "a" and writing the name "Coco," so as to minimize the risk of confusion—now too common—between the palm and the product of cacao, so universally known as "cocoa" nibs, paste, cakes, &c. We may add in conclusion that Mr. Treloar pays a well-merited compliment to Miss Marianne North and the very fine gallery of MARIANNE NORTH'S Paintings of 'Plants and their Homes' at Kew—our inspection of which under the kind guidance of Sir Joseph Hooker, is one of the brightest recollections of an enjoyable holiday trip. Should Mr. Treloar have occasion to publish another edition of his little book, we would recommend him to get a copy of the latest edition of our "Ceylon Handbook and Directory" for statistical purposes, while we shall take care to send him a copy of our own "Coconut Manual" in acknowledgement of the present gift from his publishers.

SCENTING TEA—Hon. R. B. Downall writes:—"I noticed the other day that to a letter on "Flavoring Tea" you added a footnote that doing so by the aid of flowers was unknown here and in India. I have seen the flowers of jessamine and orange used for this purpose in a tea factory in India." We have since learned from a Ceylon planter that experiments in scenting Ceylon teas have also been made, but the market for such teas is so limited that the practice was not persevered in.

RICE AND TIMBER.—A Maskeliya planter prefers the following enquiries:—"Can you oblige me with the following information? What is the duty on rice exported from Indian ports? also from Burma? Is it the same rate if shipped to Ceylon, as if to England or elsewhere? Can you tell me the Sinhalese name of the 'sau tree'? You mentioned it in your paper, I think, but I cannot recollect it, though I fancy it was kappal-gas; if so, that may mean any tree fit to make dhoneys out of, and is not distinctive enough to enable one to get an ordinary Sinhalese to collect seed." The duty on rice exported from British India, including British Burma, to any other country is three annas per Indian maund of 82 2-7ths lb. avoirdupois, or 14·37 cents per bushel of 65 lb. The Sinhalese name of *Albizzia stipulata* is "Kabalmara" or "Hulanmara,"

Correspondence.

To the Editor of the "Ceylon Observer."

A NEW WAY OF WITHERING TEA.

Calcutta, 7th April 1885.

DEAR SIR,—At present I am down in Calcutta as Ceylon folks would call it "on the spree," but such is not my intention. I have made a most wonderful discovery in tea picking and tea withering. The tea-picking machine is a secret I retain, but the withering I give to the world. I have found that on common "gunnah" or coconut matting leaves of *sathi* tea withers not only remarkably quickly but superlatively well when placed on a dry surface in the sun. What is called in Bengal Creuton tea actually improves in bouquet and also liquor when dried in the sun on coconut matting more than when it is withered in a *pucca* oven or house. If the coconut matting is elevated on rods or *bulstros* and not allowed to touch the ground, the tea is infinitely stronger and more valuable. I am at my garden placing coconut matting about 39 inches off the ground on props or *bulstros* in sizes or lengths of one hundred yards, and intend to dry as much by the sun as in the withering-house. Grey gauze must in Bengal be spread about six inches above the tea to prevent the puggah-fly (a small and mischief-making gnat) from depositing her eggs on the tea to wither. I have always received so much information from your *Observer* that I have been induced to send you this.—I remain, yours truly,

GEORGE FENTON LOCKWOOD,
of the Backarala Tea Estate, Darjeeling.

[We give the above as it has reached us, but we should like to hear what the quality and value of tea withered wholly in the sun is. Such a process was common enough in India, when it paid to make green tea; but we are not satisfied that it will answer for black.—ED.]

HEAVIEST COFFEE CROP SET ON YOUNG COFFEE.

Badulla (or thereabouts), 19th April 1885.

DEAR SIR,—I repeat my question: What is the greatest amount of crop known to have set on one year to 15 months old coffee? and in what district? Mr. Irvine's letter is interesting, but he does not, I think, come to the point. He gives a crop from 2 years and 2 months old coffee; a crop from 2 years and 3 years old coffee.

The 8 cwt. per acre in Pussellawa is from coffee planted in the S. W., and, if the crop that was picked as a maiden was an autumn crop, this coffee was 2 years and 6 months old. The "Hangranoya W. King's" seems rather vague. Then the crop which Mr. Irvine "stood in the field and saw" seems a 'bumper' with a vengeance, but is it any bigger than was picked on a certain estate not very far from Elkaduwa?

I know all about the concluding paragraph, and that is just the point: how much per acre has been known to set? The trees must have been small, and the berries could have been counted even if they were like very small peas. Never mind about the dropping off. Five to six cwt. on trees 15 months old not uncommon in Uva some years ago! Now, is this a joke of Mr. Irvine's? A stump planted, say under most favourable circumstances, in October-November would scarcely have a *spring* blossom, *i.e.*, in the following March—would it? It blossomed therefore in the autumn to the extent of 5 or 6 cwt., *i.e.*, when it was less than a year old. It is wonderful indeed, but at any rate there is the precedent of Aaron's rod.—I remain, yours faithfully,

THE ENQUIRER.

TEA-DRYING: No. 3 SIROCCOS.

Colombo, 22nd April 1885.

DEAR SIRS,—That the Sirocco No. 3 will do and does the full amount of work claimed for it by Messrs. Davidson & Co. is evident from the enclosed extract from a letter dated the 20th inst. from Mr. Jas. Wight, Kandaloya, Nawalapitiya.—Yours faithfully,

W. H. DAVIES & Co.

(*Extract.*)

I am now much pleased with the No 3's. One is sunk 7 feet, and the other is on a level with the floor, but both seem to work equally well. They were timed a short time ago in the middle of the firing and gave a result of 80 *lb. dried tea for one hour.*

CURING AND PACKING TEA IN COLOMBO.

22nd April 1885.

DEAR SIR,—Permit me to point out a few mistakes Mr. C. W. Horsfall in your issue of 20th instant makes in replying to my letter of 13th *in re* tea hulking and packing in Colombo. First, with reference to weight of empty shooks, it is impossible with unsorted tea to put more than 45 lb. in a full chest unless the tea is pressed into the chest, and this would mean a considerable percentage of inferior tea broken so that it would in sorting be mixed with the smaller and finer qualities to the detriment of the latter. If then a chest into which 90 lb. of sorted tea can be packed holds only 45 lb. of unsorted, it stands to reason double the number of chests will be necessary to convey the crop to Colombo. In the case of a crop of 9,000 lb. tea, the carriage on 200 chests from Colombo to estate would fall to be paid instead of on 100 chests where sorting and packing is done on the estate. There would also be additional carriage to Colombo from the fact that, whether by cooly, cart or rail, only 45 lb. of tea can be carried in a chest weighing 23 lb.

I attempted in my letter of 13th to show that the only apparent *saving* was about half a cent per lb. in sorting, and refrained from going into details of the extra cost of carriage as explained above and Colombo charges for sorting, refiring and packing, which would include interest on machinery and buildings, supervision of mills and in all probability the same number of men as would be required for the same work on the estate. How many men, might I ask Mr. Horsfall, would he set free from a factory in which an Ansell's sifter is at work doing from four to six maunds tea per hour? This as well as the saving on the probable cost of a portion of the drying apparatus might with advantage be left out of the discussion. Monday being an off-day with the drying machinery, all final firing and packing is best done on that day. I quite admit that sorting and packing could be as effectually accomplished—the latter process perhaps better—in Colombo as on the estate, but only at an enhanced cost to the producer.

S.

FIBRE PLANTS AND MACHINES.

SIR,—Last year there were several trials at the Zoological Gardens at Calcutta by the Revenue and Agricultural Department, in the extraction of fibres. The object of the trials was to test the fibre-extracting machines, and to make known some of the many fibre-yielding plants which are little recognized in commerce. Can any of your numerous readers tell me the result of the trials and the outcome of the attempt to make known new fibre-yielding plants in India?—Yours truly,

CULTIVATOR.

[We quoted the result of the trials, showing that Death & Elwood's machine, though not perfect, was

the best. Mr. Minchin's letter published the other day shows how limited the number is of plants from which fibre can be profitably extracted by means of machinery. We do not know that the list may not be confined to the green aloe (*Fourcoya gigantea*), the Moorwa (*Sanseviera Zeylanica*), and the rhea grass or ramie.—ED.]

HINTS ON TEA-MAKING IMPLEMENTS AND MACHINERY.

SIR,—One of the important processes of tea-making is the *withering*. It is of no little consequence, that this process should be somewhat under control, so that it may arrive at completion at a convenient hour, not too late, nor too soon. It is inconvenient to have all the machinery waiting for the withering, and not quite consonant with either convenience or comfort, that a planter had to get up at one, two, or three in the morning to call his coolies to work, to suit the withering. This process is one, that may be well under control, where a planter has got tea-drier-heated air, or other heated air at command. The quickness of the process depends on the *dryness* of the air. Not merely on the temperation, though that has something to do with it; the *dryness* of the air is the chief thing. With a clerihew arrangement and fan, the speed of the fan could be regulated to regulate the withering. Or, by turning on the heated air from the tea drier, the process might be expedited, and by turning it off, and if need be saturating the air with a chinchona waterer or other spray producer the process could be delayed.

But to do any of these with any thing approaching to accuracy some implement to *measure* the *dryness* of the air must be used. Mere temperature is no measure of dryness. Air at 60° may be very dry, while air at 100° may be at the point of saturation. Some hygrometer must therefore be used to test the *dryness* of the air used for withering the leaf. Perhaps no simpler or better can be got than *the wet and dry bulb thermometer*. These can easily be procured at any shop, or one can easily be constructed by using two thermometers, that are fairly accurate. Wrap a piece of rag round the bulb of one, and keep the other end of the rag in water, in a small cup fixed to the thermometer, and kept full of water. As the air when dry allows of rapid evaporation from the rag on the bulb and this evaporation cools the bulb of the thermometer, the mercury in the wet bulb tube descends, so that the difference of the reading of the two thermometers shows the dryness of the air. Some calculations are needed for great accuracy, but for withering purposes the observation of the difference will probably be enough. In this variable climate the differences may be from 2° to 20°. At 2° the withering would be at a standstill, at 20° difference it would be rapid indeed. A few experiments with such an instrument, and comparison of its indications with the withering of the leaf, would enable the planter to have a pretty accurate idea of how to regulate his withering.

After withering comes rolling, *ergo* something must be said about rollers. Of these there are numbers of competing machines. Perhaps the "Excelsior" and the "Universal" are considered the thing by most planters. They roll well but have very serious defects. They are wrought by a very peculiar crank, which wastes power prodigiously. This crank is ingeniously contrived so as to produce a perfectly circular motion, *i. e.* any point on the box describes a perfect circle on the bottom. This result is obtained at an enormous waste of power in working the peculiar crank. To estimate this we may regard the crank, that works the bar and bottom as a lever with the power applied at the middle of it. The box moves in a straight line only and the bottom moves in a straight line at right angles to the box. As the cog-wheel revolves dragging on with it the crank, there are four points in the revolution, where the power is working perpendicular to the lever, and consequently the power applied acts alike at both ends of the lever each end having the half, *i. e.* if the power be eight horse-power each end of the lever is moved by four horse power. One end is free to move in the direction of the power, the other not at all, so half the power applied is wasted at those four points of the revolutions. At other four points, where the power acts in the direction of the crank, the power actually in use is about five-eighths of that applied, and between these points it varies from (½ to ⅝) a half to five-eighths of the power applied. But this is by no means all the waste. The power working the box is applied at one side, and the guiding slides are at the other, involving something like a three-eighths waste of power there also. And this wasted power is not simply got rid of, it goes to increase friction, which consumes more power in overcoming it. Again the working of the crank has been in this way calculated on the supposition, that box and bottom need equal power. Probably however from its greater weight, and the side thrust of the power applied to moved the box, it needs twice the power needed for the bottom. Consequently there will be two points of each revolution, where a great accession of power is needed, and two where it is at a minimum thus requiring a fly-wheel of considerable size to get uniformity of action. Taking all things into consideration, it would perhaps be no exaggeration to say, that, on account of this peculiar crank, out of eight horsepower applied to drive the machines somewhere about three horsepower is actually effective in the work, for which the machine is devised. This comes to be a very serious question for a planter, who has got a waterwheel fitted for producing three or four horsepower, while an excelsior may need eight. It means a new wheel or a steam-engine or a turbine, as the case may be. And when we come to consider further, it appears that the advantages of the use of this crank are merely theoretical, but of no practical value. It may be that a perfect circle is more beatiful than an imperfect figure. But tea, at least, Ceylon tea does not seem to be over-fastidious on that point. Kerr's and Jackson's hand-roller that effect an ovate or other deviation from the circle produce as satisfactory a roll. Another crank could easily be applied, producing a sufficiently good approximation to the circular motion, and not liable to the charge of such a great waste of power. I have gone at length into this point, as it is a matter involving very serious considerations in the economical working of tea estates. Kerr's machines are generally allowed to do good work, but complaints are made of the gallows, and of the brush action arrangements getting out of order. Why does not Kerr enlarge his machine and do away with the gallows and perfect his brush action, and thus compete favourably with either Universal or Excelsior? The saving in power and in prime cost is all in his favour. I suppose there are other good machines which I have not seen. However, the machines of the future, which is to supersede all others, must be a *continuous acting* one, taking in tea at one end and giving out roll at the other. Inventors set your wits to work on this desideratum! Some I believe are busy planning. By and bye Ceylon ingenuity will be to the front.

After rolling and fermenting comes drying. So we must have a word about driers. The preponderance of votes seems to favour the No. 3 Sirocco. It seems to have many advantages over others. But there seems also a considerable defect in it. All experiments in drying seem to point to the ad-

vantage of a rapid change of air. Some machines effect this by a fan, some by a chimney, either way may be good. The No 3 is lacking in either. The height of the funnel, that gives current to its heated air is only about eight feet. That, of course, will not give a rapid current, and this has to be reduced to a fourth as the area of the mouth where the air passes through the tea is four times the area of the funnel. There are only two series of trays for the air to pass through, compared with four and more in other cases, but it seems likely that a greater speed of current would be an advantage.

This could easily be got by using a fan to drive the air in at the bottom of the machine. An air-tight chamber of galvanized iron round the vent holes at the bottom, with which a fan communicated would effect the whole thing without interfering in the least with the working of it, as it at present stands, and all experience points to good results from such an arrangement. A fan, of course, needs driving power, and the waterwheel is not always working the roller while the drier is in operation; some other driver must be at hand for the continuous working of the fan.

Mr. Cameron of Ythanside, who has favoured the planters, through the Dimbula Association, with so many ingenious devices, has the plan of a turbine at once cheap, effective and not liable to damage or getting out of order, which would do well for such a purpose. For a few rupees and with the spilt water from the sluice, this improvement on No. 3 might be effected. The new Jackson's drier with revolving bands I have not seen. The idea seems a good one, however. Perhaps it too might be improved by a Cameron's turbine and fan. When I know more I 'll tell you MORE.

PROPORTION OF LEAD FOR TEA CHESTS.

24th April 1885.

DEAR SIR,—You asked recently—or one of your correspondents did—how many lb. of lead lining went to a chest, and you answered the questiot yourself stating that about 6 lb. went to the chesn.

I find that by using chests 24 20×18 instead of 24 19×19 I can do with very little over the 5 lb. of lead per chest using Johnson's 5 oz. lead 84″×22″. 24×20 18 = 5 cubic feet exactly, whereas a small fraction is involved in 24×19×19 Similarly for half-chests 18×16×15 = 2 50 cubic feet exactly, and suits the lead better than 16¼×16⅜×16¼.—Yours, C. W. H.

PREPARATION OF TEA IN COLOMBO.

April 25th, 1885.

DEAR SIR,—As "S." and I are at one on the two main points under discussion, viz.—1, that tea sorting and packing might be done as well if not better in Colombo than on the estate, and 2, that it could only be done at an enhanced cost to the producer. matters of detail in which we may seem to differ are of secondary importance.

If, however, mistakes have been made on either side on matters of detail it may be worth while to inquire how far they affect the main result.

If tea is to be sorted in Colombo, "S." is quite correct in insisting on the necessity of transporting it from the estate is such a manner that the finer qualities shall not be injured by the admixture of inferior leaf through breakage of the latter *en route*. To prevent this he would pack only 45 lb. in a 90 lb. chest. I venture however to suggest that as much if not more breakage may occur by tea being packed too loosely as by being packed too tightly; and to secure that the contents of the package should not too much knocked about during the journey I would prefer to have from 60 lb. to 65 lb. of unsorted tea packed in an ordinary 90 lb. chest. At this rate only 150 chests, and not 200, instead of 100 would be required to bring down the crop of 9,00 lb. which "S" takes as an example. There would then be rail fare up and down on 50 chests above the number on which it is now paid. A chest weighs, let us say, 23 lb., or, with lining, say 28 lb. The weight of 50 chests would therefore be 12½ cwt. Now at 2nd class rates the rail fare to Talawakelie up and down is R26·39 per ton: on 12½ cwt. this would be R16·49 each way, or in all R32·98. "S." calculates the saving on sorting by doing it in Colombo at ½ cent per lb. which on 9,000 lb. = R15. If the railway would take return shooks at 3rd class rates the carriage on extra packages would amount to only R25·56.

My contention was that the saving in sorting would more than cover the carriage on extra packages; and this I think is shewn by the above figures to be the case—provided as much as 60 lb. of unsorted tea can be packed in a chest measuring 24×20×18 or 5 cubic feet giving an inside capacity of 4·80 cubic feet.

The *few* mistakes therefore seem to be limited to this one, if it be a mistake at all, that I have assumed that more than 45 lb. can be put into a 90 lb. chest.

"S." asks how many men would be set free from a factory in which an Ansell's sifter is at work. I will suppose, merely for the sake of argument, that only one man would be set free; and the unit will be convenient to work with: but what does this mean? In the case of Abbotsford for instance it might mean the value of 20 lb. leaf per day or more —say 5 lb. of made tea worth at least 50c. per lb. or R2·50. I observe that Mr. Seovell stated the cost of rolling, firing, sifting (in which I presume sorting is included), and packing, including boxes and tea-house sundries, on Strathelie at 5·47 cents per lb. It would be interesting to hear from him what the cost of each of these operations was separately. I presume that 5·47 is the bare cost without counting "interest on machinery and buildings or supervision," items to which "S." calls attention in his letter of the 22nd instant.

In a former letter I alluded to the possible employment of some kind of airtight and waterproof bag or double bag for the transport from estates of tea intended to be finally dealt with in Colombo. If this description of bag could be devised, I am aware that there would still be the objection of the liabity of unsorted tea conveyed therein to breakage. This objection would however disappear, or be greatly minimized, in the case of *sorted* tea which was merely intended to be *packed* in Colombo.

I quite acknowledge the competency of "S." to discuss this matter and the general accuracy of his statements, saving only that one in which he says I made "a few mistakes."—Yours faithfully, C. W. H.

THOMPSON'S CHALLENGE ROLLERS.

The Ceylon Purchase Hire Company,

Colombo, 1st May 1885.

DEAR SIR,—Our attention has been called to the following paragraph in your Senior Editor's article "Seeing the Tea Grow," in your issue of the 22nd April:—"I may say that I saw in the course of my travels a Thompson's Challenge Roller, but that I heard nothing in favour of its 'most peculiar' principle." In justice to the inventor of the machine, we think it necessary to call attention to the following facts. According to Messrs. [illegible] Low Tea [illegible] January 12 [illegible] are putting to 2,295 packages, and the teas from the Challenge Roller *topped the list* with an average of

1s 10½d. In February 24 estates sold 1,378 packages, and teas from two different estates come in *fourth* on the list. In March 58 estates sold 2,843 packages, and teas from the Challenge are *second* in the list with 1s 10½d (next to Loolecondura with 1s 11¼d average), and another estate's teas from same class of machine fetched an average of 1s 5¼d.

These facts, some planters think are rather in favor of the machine's "most peculiar principle." What do you think?—Yours faithfully,

W. H. DAVIES & Co.

[We could only speak of the specimen we saw and heard of on "Mariawatte," the one we suppose with which the celebrated trials were made. We should like to hear what Ceylon planters have to say from experience about the "Challenge."—ED.]

PREPARING TEA IN COLOMBO DENOUNCED AND THE UTMOST ECONOMY ADVOCATED.

Colombo, 2nd May 1885.

SIR,—Middlemen are the bane of many industries, and tea is certainly one of them: the fewer we have of them the better, and you may rely upon it that by far the cheapest way of dealing with tea is to pack it on the estate and dispatch it direct to the nearest point to the ship. Every cent per pound added to the cost of tea is a nail in the coffin of the industry.

The only hope for Ceylon tea is, that planters under the pressure of poverty will practise extreme economy in every item of cost to enable them to compete some four or five years hence with India and Java.

The day may come when the London average of Ceylon tea will be 9d per lb.; on that day, the unnecessary expenditure of a cent or two per lb. will be a grievous burthen on the industry.

I write with some knowledge of the subject when I say that tea cannot be re packed, garbled and refired in Colombo, except at a considerable addition to the cost.

Merchants will not work without remuneration, and we know what that means.

Can tea be put into boxes, or shooks, and nailed up on the estate without any expense being incurred? Can these boxes be re-opened, re-weighed, re-packed, re soldered, re-marked, conveyed backwards and forwards without cost? to say nothing of the cost of re-firing and the interest on machinery.

It may suit "C. W. H." who is a tea-mixer and garbler to advocate additional manipulation in Colombo, but, depend upon it, the fewer people who meddle with the tea after it is made the better. "C. W. H." reminds me of a certain Frenchman who went to war with a light heart.

Labor may be a little dearer on estates than in Colombo, but the difference would add very little to the cost of picking out the red and unsightly leaves. These will never be any scarcity of teahouse coolies, however scarce field laborers may become. A class of laborers can be obtained for teahouse work which *cannot* work in the field.—Yours truly,

T. P.

SIR JOHN LUBBOCK has communicated to *Nature* a letter, received through Mr. Grant Duff, the Governor of Madras, detailing observations in various parts of India, Burma, and Siam, which have shown that the southern chestnut woodpecker, and also allied species, use ants' nests for breeding in. It seems to be doubtful whether the ants desert the nests after they are taken possession of by the birds, ants having been found in nests in which the birds' eggs were partly incubated. Two species of kingfishers have also been observed to build in ants' nests.—*Bombay Gazette.*

BLACK BUG in Rakwana appeared on Liberian coffee and spread from it to the Ledger cinchonas which are covered with it, but strange to say it has not touched the succirubras in the same field, nor the Arabian coffee! To the vagaries of bug there is no end.

THE REPORTED SALES OF CEYLON TEA are, sometimes a mystery. In the case of a recent sale of Abbotsford the agents sent accounts showing the sale of every chest of an invoice at good prices rising to 1s 10½d for broken pekoe. In the Prices Current, a portion only of the pekoe is reported as sold at 1s 5d, but not a word about the 1s 10½d.

PEARL OYSTERS.—One result of the dry weather has been, that the natives report large quantities of seed pearl oysters forming in Labuk Bay; these oysters it would seem grow only on the mud deposits at the mouth of rivers, but are destroyed by too great an admixture of fresh water. Should there be but moderate rains during the next two months a somewhat large crop is expected, if there are heavy rains however, these hopes may be disappointed.—*British North Borneo Herald.*

BRAZIL COFFEE AND THE UNITED STATES.—General interest centres in the result of the present yield of coffee in Rio, about which there is still doubt, but another important point upon which the future of the article is very dependent is the position in the States. The feeling is strong that the large deliveries of last year reflect pretty accurately the true consumption, and a couple of months ago the figures we printed, giving the returns for many past seasons, rather confirm this view. It is held however in some quarters that the heavy deliveries of the past two months are beyond immediate requirements, and that the trade are stocking up, the direct business between Rio de Janeiro and St. Louis, Chicago, and other important cities in the interior, having been stimulated by the competition amongst dealers and importers, as well as amongst the railway lines. It is instanced that in January a steamer arrived at Baltimore with 30,000 bags *Brazil*, and of this shipment 22,500 bags were dispatched direct per Baltimore and Ohio railroad to western points, the largest quantity ever forwarded from that port. Subsequently another steamer brought 15,000 bags on through Bills of Lading to the west and south-west, apparently a large part of the supply is being absorbed in this manner.—*James Cook & Co.'s Weekly Dispatch*, March 27th.

THE INDIAN INDUSTRY, says the *Pioneer*, which ought more than any other to profit by the London Exhibition is the tea-trade. Though the demand for Indian tea in England is on the increase, it is still comparatively little known, even in London, among ordinary consumers. Yet to their tastes, after all, every commodity must appeal as to a final court of judgment. If, therefore, arrangements such as were partially in force at the late Health Exhibition are made on a vastly extended scale, and to the exhibits of each variety of Indian tea, stalls are attached, where at a low price any visitor can be provided with a cup of really good Indian tea, he would in all probability during the next few days speak constantly of having enjoyed at the Exhibition the "best cup of tea I ever tasted in my life." Arrangements should also be made for supplying unlimited numbers of sample packets—not too large to be carried in the hand or pocket without inconvenience, and costing, if possible, only a few pence—of the very best qualities of tea. These may seem insignificant details, but when the possible purchasers have to be calculated at 50,000 daily, and in the aggregate by millions, coming from every country in the world, planters and traders will see that these details become of vast importance. There is probably, and notwithstanding the present depression in it, a great future before the Indian tea trade; and the London Exhibition of 1886, if properly utilized in its interests, should bring that future sensibly nearer.

THE GRAIN AND PULSE TRADE OF INDIA

has enormously increased in the past five years, the rise in value having been from R98,608,000 in 1879-80 to R176,000,000 last year. We are quoting the figures from Mr. O'Conor's review. Large exports of wheat took place last year, but these are now checked by the good harvests in Britain and elsewhere, so that wheat in Europe is cheaper than it has been for a century. Not far short of 50 millions of cwt. of grain were exported from India last year, the figures being 49,217,863 cwt. against 25 millions five years ago. Grain, indeed, represented 20 per cent of the whole export trade. Reduced to tons the export of grain was 2½ millions of tons, of which rice constituted considerably more than one-half, viz., 1,352,000 tons. Mr. O'Conor shows that the exports of husked rice went up from 21,908 000 in 1879-80, valued at R83,416,000 to 31,029,000 cwt. valued at R84,400,000 in 1882-83, going down last year to 26,832,000 cwt. valued at R83,300,000.

It is very sad and, by no means pleasant to spirit drinkers, to learn that so much of the alcoholic drinks sold as grape-brandy, whisky, gin, &c., owe their origin to rice.

Since the famine year, the rice trade was not so unsettled as last year and it seems that even rice was superseded in France for distillation purposes by the comparative cheaper price of maize. The exports of wheat from India had risen from 2,195,000 cwt. valued at R11,210,000 in 1879-80 to 20,956,000 cwt. valued at R88,775,000. But the export has been checked by low prices.

The large accumulations of gold and silver in India show that but a small portion of the imports have of late years been paid for in money, and as railway facilities are increased and cheapened, there can be no doubt there will be a steady export of wheat from India to Europe at remunerative prices. A quantity equal to 55,647 cwt. of wheat last year sufficed for the wants of Aden, Arabia, Ceylon, the Straits and the Mekran Coast. It is interesting to learn that Indian wheat is used for the manufacture of maccaroni in Italy and gives satisfaction.

Amongst the pulse exported is the "gram" on which horses are so largely fed in Ceylon.

LETTERS FROM JAMAICA.—NO. 4.

CINCHONA PLANTATIONS IN THE BLUE MOUNTAINS—COFFEE—LAND SUITABLE FOR ORANGES AND CACAO—POOR COFFEE CROP—HOW TO MAKE COFFEE PAY—JAMAICA ENGLISH.

Blue Mountain District, 28th Feb. 1885.

In my last I said I should refer in my next letter to what had been done in cinchona in the Blue Mountain District. First and foremost comes the Government Plantation at "Cinchona," 150 acres in extent and from 5,000 to 6,000 feet above sea-level, in fields of different ages and varieties of the tree: this has been a great success, and but for the low prices now ruling would have been a small mine of wealth to the Government and added to the public revenue. The next largest estate is that of the Portland Gap Company; then "Iron River," "Wild Wood," "Moy Hall" and "Cleveland" owned by Mr. Marshall, an old Ceylon planter. These were opened as pure cinchona estates; in addition most of the old estates have planted cinchona fields. I do not hear of any large extension to these properties, so that Jamaica is not likely to add much to any over-production, though the quality is sure to be good, and will, I trust, always yield paying prices. One or two of the cinchona proprietors, since the fall in price, have taken to cultivate coffee as well. These are on the northern slope where there is any amount of available forest land suited for coffee and cinchona cultivation, calculated at one time by Mr. Morris as 40,000 acres; it is mostly steep, but the soil is splendid, and, were it only made accessible by good roads, and were labour more cheap and plentiful, would no doubt soon be bought up and cultivated. At the foot of these hills, are lower and less steep lands, which would do very well for orange and cacao culture; but Government has no capital to open good roads, though they would soon repay their cost by the enhanced value of the land.

As to coffee, the crop off the lowlands is now well over and the top commencing. I believe the settlers have had a very poor and light crop on this side of the island in consequence of the dry summer that prevailed and made so much of the coffee to float when put into water. Most planters buy this coffee in the cherry, and pulp and prepare it themselves for shipment, and, as it is bought for about 40s and sells at from 70s to 80s per cwt. according to quality and colour, must leave a very fair profit after deducting all expenses. As to the crop off the upper fields, it is early to speak decidedly, but the impression seems to be that it will not be a heavy one. I am of opinion that 5,000 feet is too high an elevation for coffee in Jamaica, and that, as in Ceylon, 3,000 to 4,000 is the best. Crops from the high fields appear to be uncertain, whereas at medium elevations they are far more to be depended upon. A neighbour of mine has had 7 cwt. an acre from his young coffee, which proves Jamaica coffee would give good and paying crops, were not the old coffee so full of vacancies. If but 100 to 120 acres could be got in these mountains, in one field, and not too steep, it would be a very paying property, at the prices now ruling for Blue Mountain coffee. The best estate in Jamaica, as I have previously mentioned, is a paying property: why should others not be made to do the same, with proper care and cultivation?

I will now give you some specimens of Jamaica English: it is most difficult for a new comer to understand what the people say, and even now after 13 months' experience, I cannot always take in what is said. To begin with estate words:—A mammotie is hoe; quintanie, gravel hoe; cattie, cutlass; forest, bush; horses and cattle, stock; water-course, gutter; ravine, gully; lines, barracks; store, the works; superintendent, busha; conductor, bookkeeper; landslip, washaway; bungalow, great house; one row running in'o another, buck's up; to knock against accidentally, to bounce up against; spade-bar, digger; coffee tails, trash; bushel or box, tub; young plant, sucker; drying coffee, sunning; peeling coffee, grinding; weeds, grass; road, pass; hill, mountain; vacancy, gall; crush or smash, mash; to be like a thing, favors; pig, hog; to be too close, bunch up; quickly, brisk.—Yours faithfully,

W. S.

THE SCIENCE OF TEA PREPARATION.

From an able paper contributed to a local contemporary we quote the practically interesting portion which deals with the preparation of the tea leaf after plucking, omitting only the introduction which gives the physiology of the tea plant:—

Whenever the leaf is detached from the shoot, a difference of temperature is the immediate result. Water is given off in the form of vapour by evaporation, which causes a reduction of temperature in the leaf. In the process of rolling, the epidermis is broken up, and the substances forming the cell walls of the cellular and vascular tissues are *mashed* up with the vegetable juices of the cells. Chemical

decomposition of the organic structure at once takes place: oxygen is absorbed, and carbonic acid gas is given off, generating spontaneous heat amongst the particles of the mass. The rise in temperature increases, as the roll is squeezed together, and would go on until the spores of putrefactive fermentation became developed. This is prevented by breaking up the bulk at the proper moment, spreading out the leaf, and exposing it to atmospheric evaporation, which again reduces the temperature. What is now required is a vacuous atmosphere to promote speedy evaporation, for the greater the force of evaporation, the greater will be the degree of cold on the surface of the leaf. What I mean by a vacuous atmosphere is an atmosphere deprived of its own vapour.

The object in squeezing the leaf into balls is to suspend evaporation and submit it to the influence of *sweating* caused by the absorption of oxygen and the expulsion of an equivalent volume of carbonic acid gas. This removes the sourness of the leaf by changing a portion of the organic acids into glucose or grape sugar. It may be called a process of insensible fermentation, although it is in reality simple oxidation. True fermentation is caused by the sporules or seeds of living bodies which always float about in the air, and, in entering into the mass of leaf propagate themselves, and in the act of development cause putrefactive fermentation. If the air of the compartment in which the roll is made could be filtered before passing into it, these sporules would be prevented from entering, and the tea could be preserved for any length of time without the slightest chance of putrefaction. But, on breaking up the rolls, even although they should happen to be oversweated, if the leaf could at once be exposed to vacuous air, the temperature would be so suddenly reduced by the force of evaporation that any germs of true fermentation which might have been propagated would be instantly killed.

In the process of rolling and sweating, or so-called fermentation, the leaf undergoes a state of oxidation, and becomes darker and darker in color the longer it is exposed to the air previous to firing. This discoloration is caused by the influence of the light and air acting upon the tannin or tannic acid of the leaf. Tannin, which is the astringent principle of the leaf, differs from the active principle—theine—in chemical composition: the former consists of carbon, hydrogen, and oxygen only, while the latter contains a large proportion of nitrogen in addition.

Tannin in a state of solution rapidly absorbs oxygen, and its astringency becomes weakened the longer it is exposed to the air by resolution into glucose and gallic acid. In the process of firing, the gallic acid is again split up into carbonic acid gas and pyrogallic acid, or what is termed *trihydroxyl benzene*. Tannic acid is also formed into pyrogallic acid when heated to 215 degrees Cent. The former has the property of forming a permaneutly black oxide with rust, or any *ferric* substance, and care should be taken that the leaf, from the time that it is picked until it has been fired, is never allowed to come into contact with iron, not even with the head of a nail in the rolling table, as it will leave a black mark on the leaf, which, after infusion, would make the outturn present the appearance of the tea having been burnt in firing, though that should not be the case.

Tannin is very soluble in water, and in the process of infusion becomes completely dissolved, and should leave the outturn of the leaf a uniform fresh copper colour.

The secret of success in the manufacture of good tea, I think, lies in expedition—I mean in the processes of of withering, rolling and sweating—for if these are pro- longed, the active principle—theine, coosisting largely of nitrogen—volatilizes and flies off as ammonia gas. Strength, pungency, and flavor can only be preserved by expediting these processes.

Rapid firing is, in my opinion, detrimental if the heat is obtained directly from fuel or from hot air, as it commonly exists in the atmosphere, for the simple reason that the astringent principle is burnt out of it by being suddenly exposed to a temperature of 215 degrees, changing the tannin into pyrogallic acid, and for the same reason I consider it is injurious to attempt firing more than two or three trays at a time, for the steam arising from the lower trays dissolve a portion of the tannin before it has become *fixed*, and, besides, the firing of each tray throughout cannot be accomplished under a uniform degree of temperature.

Speedy fermentation, or sweating of the leaf, depends upon a proper condition of the withering, and this depends upon the hygrometrical condition of the soil and of the atmosphere at the time the leaf is picked. In seasons of drought great attention should be paid to the withering process, for at that time there will be much less sap in the leaf and less moisture to evaporate than would be the case during, or immediately after, rain. Consequently, if the leaf is overwithered, the juice becomes so thick by the time it is ready for fermentation that it will not ferment properly, no matter what the condition of the atmosphere may be. If the rolling and fermenting operations could be conducted in chambers of dessicated atmospheric air, I do not think it would be necessary to wither leaf more than just enough to prevent it from breaking in rolling, but, until we have special compartments for withering leaf in dry atmospheric air, in wet or dry weather, it is impossible to lay down any precise rule for guidance. The best test can only at present be obtained from experience.

For the process of withering and fermentation, thermometers placed in the tea-house, or anywhere, are of no practical use, for the degree of *thermal* heat indicated by them is no criterion of the general conditions of vapour heat, which exercises the greatest influence on these operations. With an apparatus to absorb moisture as quickly as it forms, every operation could be carried on with mathematical precision in any kind of weather, but common atmospheric air contains at all times from 50 to 70 per cent of the quantity of vapour necessary to saturate it, and, if this proportion does not exist within these limits, the atmosphere is either uncomfortably hot or stewy. R.

On the principles here enunciated, we feel more than ever convinced of the value of appliances for removing foul and hot air and moisture from leaf-withering and roasting manufactories. The adapted Clerihew is, no doubt, useful, but we know of nothing so rapidly and completely effectual as the Blackman Air Propeller.

CULTIVATION OF COFFEE, TEA, AND CINCHONA IN MALABAR.

(From the *Field*.)

Sir,—Now that attention is being directed to the cultivation of fibrous plants, more especially rhea, it may not be out of place to say a few words with reference to such other products as require similar climatic conditions. It has been justly maintained that few districts are better adapted to the cultivation of rhea than Malabar, situated on the Western Ghauts of Southern India. The climate is in every respect suitable, the soil is good, labour is cheap and abundant, and transport charges to and from the coast compare favourably with those of other districts. This applies not only to rhea, but equally so to coffee, cinchona, tea, &c. To commence with coffee. Ah! but people say, coffee does not pay to cultivate, and upon the face of it, there is much to say in support of this contention; but it would not be difficult to show that coffee has been made to pay, and pay well, and that under circumstances as adverse, or even more adverse, than those existing at the present moment. Twenty years ago a planter considered himself a fortunate man if he got thirty rupees per cwt for his coffee on the coast; now he would consider himself very unfortunate in having to accept that price. Yet today the cost of labour is not greater, while carriage to and from the coast is less. Coffee paid then, why should it not pay now? The answer is not far to seek, strange though at first sight that answer may appear to be. I say advisedly, the high prices that were experienced some few years ago, and which led to a large area of land being planted which under no condition was suitable for the cultivation of coffee. Something also must be put down to reckless expenditure, the child of temporary prosperity. But what about leaf-disease? I do not believe that to coffee cultivated under conditions not inimical to its growth it will do any material injury, however fatal it may have been to the class of estates referred to above and worn out properties, of which there

are many such in every district. As is the case in all epidemics, the aged and the infirm are the sufferers. Taking the most adverse view of coffee, it is no worse than it was twenty years aga, when it was considered a good investment, while its prospects in the future are for many reasons brighter. The low price of coffee in 1860 tended to restrict production, which, reacting on value, led to the high rate realized in 1873. This stimulating production has brought about the present state of the coffee market. As it has been in the past, will it not be in the future? Have we not evidence of this already in Ceylon and elsewhere? Old and worthless estates are being abandoned, while new plantations are seldom or never heard of,* and this leads to a limitation in production, to be followed hereafter by enhanced value of the article.

Looking at the fact, therefore, that land is once more cheap—that English money is worth 25 per cent more than it was in 1860, that we have a better future before us so far as prices are concerned, surely this is the time to invest money in this speculation, if ever. But this is not all that can be said in favour of the coffee planters of the future. In days gone by they had coffee, and coffee alone, to trust to. Now it is different. There are other products that can be cultivated in conjunction with coffee. Let me first speak of cinchona. This can be planted separately or in belts, or amongst the coffee. To this latter exception may be taken, as affecting the yield of the coffee; but planting coffee with or under shade means two very different things. By the former principle the heavy crops from open planting are not interfered with, the cinchona, if of a good variety, not being sufficiently large to affect the coffee, unless it is five or six years old, when its shade is beneficial rather than injurious, and, against any loss in crop there might be hereafter, you have to credit a reduction in upkeep charges.

The suitability of Wynaad for cinchona is so fully established, that I may pass it by without further comment. No less significant is the fact that, in its chief competitor, Ceylon, its agricultural success has been demonstrated a failure.† And there is no other district that can claim precedence of Wynaad either in respect of soil, climate, labour, or transport to the great commercial centres. Here there is a great advantage that the coffee planter of 1885 has over the planter of 1860.

The next product I would wish to notice is tea. This too, is now being profitably cultivated in Wynaad. A few years ago it was not supposed that it could be grown successfully at so low an elevation; but, as a matter of fact, it is more than probable that it will be found to do even still better below the Ghauts, and very little above sea level. Both in Wynaad and below the Ghauts we have everything the tea plant demands—good soil and a humid climate. It is essentially a plant that can be grown with coffee, delighting in that very aspect which coffee abhors. Thus the various slopes of one estate can be cultivated successfully.

In respect to rhea, it is full early to speak with the same degree of confidence. That wild varieties of rhea are indigenous to Malabar has long been well known, while the success that has attended the cultivation of the true variety has exceeded the most sanguine expectations. My remarks have so far, had reference to land in Wynaad, but there is equally as much to say in favour of that below the Ghauts. If coffee cannot be grown there, it is the home of the pepper vine; cinchona has never been tried At one time it was said it would not grow in Wynaad. We now know differently. But the many varieties of rubber grow there; as does cocoa, coca, and the cola nut. And what shall I say about tea? Simply, that in Ceylon, at a similar elevation, it has yielded as well as that at higher elevations, and those competent to judge predict a great future for tea below the Ghauts of Western India.

Surely I have written enough to show that Malabar is not played out yet; that there is an opening for those seeking employment with capital to invest, and to those who are merely looking for profitable investments.

A. R. HINDE.

* On the contrary, we regret to say, young coffee estates are being planted with tea.—ED.

† No: over large areas it has been a great success.—ED.

THE FATHERS OF THE INDIAN TEA INDUSTRY INTERVIEWED.

The recent correspondence in our columns on the subject of progress in tea manufacture having attracted considerable attention, we thought the occasion a suitable one to obtain the views of some of the leading authorities on the tea industry. We accordingly commence by giving those obtained during an interview with

MR. JOHN BERRY-WHITE.

"I have not the slightest objection to giving you my views, but understand that I have had many important matters to attend to during the last few days, and my thoughts have not had time to arrange themselves in a form as suitable and precise as you might wish for your purpose."

"Perhaps I can help you by asking leading questions, seeing that from your exceptional experience you must hold ripened views on those points of most present interest to all connected with tea. Suppose we commence with Manufacture, this having so recently been the subject of correspondence in the *Home and Colonial Mail*?"

A moment for consideration and he proceeded:—

"Well, there 's not the least doubt but that our system of manufacture has hitherto been conducted on purely empirical methods, in fact—by mere rule-of-thumb. The most experieuced planter, if you ask him, cannot explain the reason for one of the processes he employs. The time has come when first-class chemists should be sent out, of an order second only to Pasteur in his branch of the profession, though I do not mean that they should be *of* his branch. These should locally enquire into and discover the real objects of each process, compare notes, and then formulate the true theory of manufacture. The Government should undertake this; they did more for the cotton industry in India. Commissioner after Commissioner was sent out with a view to discovering how far the staple could be improved. Of course, the Government must be moved to take such a step, before it will act. The Associations should take this initial step and should also bear a moiety of the expense. There are various precedents for such a course as for example the several Royal Commissions for Ireland; and that the Tea Industry in India is now a sufficiently important one I fancy few will doubt."

"Do I understand, then, that you quite agree with 'Artemus' in his letter to the *Home and Colonial Mail*?"

"Yes, certainly, we require that manufacture should be conducted on a scientific basis by the aid of scientific formulæ, as many other manufactures such as brewing, sugar-refining are now conducted. There may be good cause for returning to panning discovered, as we gave it up on quite insufficient grounds, speaking of its effect on the produce rather than from the economic point of view. It was given up simply because Mr. Inskipp spent a month on a factory and could not detect the difference between samples of teas which had been panned from those which had not. That there is some actual distinctive result obtained by panning I cannot doubt, one of my reasons being that a case came to my personal knowledge where tea which had not been panned invariably caused sickness, whereas tea which had been panned could be taken without unpleasant consequences; and I am certain of my facts here, for no matter how one tried to deceive the person in question the effects were invariably as related."

"Do you also agree with 'Pace Tua's' remarks upon the possible conversion of tannic acid into gallic acid?"

"Certainly, his ideas are perfectly correct, as anyone with the most elementary knowledge of chemistry must know that tannic acid is convertible into gallic acid as he described. He did well in producing that one example, as illustrating how open our present empirical methods are to other possible faults. Thus as everybody knows, the flavour in our teas is owing to the presence of essential oils, and essential oils are all extremely volatile, and doubtless we lose in our present system of manufacture a very large proportion of these which might be saved."

"Do you blame the existing machines, or the coke, or the high temperatures employed, as some do, for the deterioration of late years?

"That, or, rather, those questions I would answer in somewhat general terms, thus: The rolling machines we have now are probably as perfect as could be desired. As regards the Dryers, it is still a matter of very great doubt whether the falling off is due to these. The old idea that the direct products of combustion were essential to the keeping qualities of tea has long been exploded by the excellent results of the Sirocco. For my own part, I very much doubt whether the falling off in the keeping quality is not much exaggerated by brokers. If the chests are opened in Calcutta, for sale there, or if they are opened here before being required, of course, deterioration sets in; but if the chests are kept intact, I know, from my own experience, that after six or seven years, it is as good as the day of packing. I would qualify this by saying that I assume the teas have not been too rapidly cured in an excessive temperature, as I do not believe in rapid firing, and do not think that rapidly cured teas can be expected to keep; as they are probably not so thoroughly cured as they are when sufficient time has been devoted to the process. Rapid firing at high temperatures also probably dissipates the volatile essential oils, and robs the tea of flavour. The old-fashioned custom, under which it took many hours to dry tea, was a great contrast to the rapid firing I am referring to. I think that the Gibbs and Barry Dryer has been unfairly abused, when abused owing to its being overworked. Its very power of doing a vast amount of work has proved a great temptation when added to ignorance of the danger of rapid firing on the part of those using it. Thus I have carefully watched the prices of a garden go down when one of these dryers arrived, and the tea-house manager drove the willing horse too fast. I have also seen that garden's prices go up in as marked a manner when the same machine was employed at a reduced temperature, and as it should be. I consider that *well-made* coke is quite as suitable for tea-drying, and practically the same thing as charcoal, hence I see no objection to the use of good coke. Thus I do not think we can blame the drying machines for the deterioration, though there may be reason at times to blame the way they are used."

"What do you think about the action of green wood on the lead of the tea-boxes *in re* the deterioration?

"What everybody thinks, at least, should think—that is, greenwood contains pyroligneous acid; this reacts upon the lead and forms acetate or sugar of lead; the lead is corroded, rendered porous, and no longer dampproof."

"Do you think the green leaf treated as it should be before manufacture, panning apart?"

"Well it is not as well cared for a nowadays as it used to be, and that is possibly one source of deterioration, but the conditions ruling are very different. The mass of leaf now to be conveyed in from the field and attended to is the cause, and one which is, perhaps, in the nature of things to be expected, and in a measure accepted."

"What views do you hold as to the commercial future of Tea?"

"I think our chief aim should be improvement in the economic questions affecting the industry. We should not rest content with the recent reductions in the cost of production. We have to accept and beat competition with other countries—notably, Java and Ceylon, especially the former. Should people in Java only become more enterprizing that source alone could turn out enough tea to supply all Europe. I think Ceylon has been over-rated. Ceylon promises to turn out a moderate quantity of fine teas, but I doubt if it will become a serious rival in the matter of quantity. [Oh!—ED.] Coming back to the cost of production; there is still great room for improvement here. Hitherto our capabilities have been handicapped by the small scale on which estates have been worked. There are some 90 limited companies on the Calcutta Register, many of these, though not turning out 1,000 chests a year, have all the expensive machinery of a joint stock company, also the European supervision and heavy agency and commission items, not to speak of the native establishments, &c., sufficient for concerns three times the size! Amalgamation is the cure for this evil. Let me illustrate this with one example, that of a concern in which I am interested formed by an amalgamation of eighteen or twenty small concerns. Originally there were that number of factories and managers, and establishments, &c. After amalgamating there were but three factories, and six European managers! I look on this, however, as but a commencement after all, yet capable of being carried very much further. Thus there is no good reason why all the estates on the Sadiya road should not be amalgamated, if conflicting proprietary interests could only be reconciled. There would then be one important concern producing about 6,000,000 lb. of tea per annum. This would effect a saving of at *least* 10 per cent., or 1d per lb., and the financial advantages would be also very considerable, as the stock would be of sufficient importance to lead to daily transactions on the Stock Exchange. This would remedy one of the greatest existing disadvantages or draw-backs to tea investments, as money invested in tea would no longer be locked-up, as at present, with no market to dispose of the shares. There is another reform, the importance of which I would emphasize. A through Bill of Lading from Assam to London should be introduced. Why should teas consigned direct to London have to be placed in a 'lighter' at Calcutta, landed, then placed in godowns, then replaced in 'lighters' to be conveyed alongside the ocean steamer? There is too much waste about this for it to exist much longer in these hard times. The Assam 'flat' should go alongside the English-bound steamer without further ado. There are difficulties in the way, but assuredly there are no insurmountable ones. One thing is safe to predict—viz., that if the present river steamer companies do not take this matter up within the four years of their contract, rivals will be found to come forward and do so."

"What effect has the Railway had in the Dibrugarh district?"

"It has greatly simplified the work of the managers, has relieved them of much anxiety and bother, and has economized the cost of working in many ways, and has also succeeded in getting produce to market a month sooner than formerly."

"Has it had any effect on the frontier trade?"

"Considering that the trans-frontier road to the Irrawaddi is closed by overgrowth of jungle, from the long neglect of our Government to keep the route which formerly existed open for commerce, the effect the railway has had is wonderful. From eleven to twelve thousand maunds a month are now carried to Margarite, the frontier terminus, where, before the completion of the railway, not a maund was carried! These goods are disposed of to the Singphos, who take them to Hukong. Wax, rubber, and other forest produce, &c., are brought from thence to exchange for Manchester and Sheffield goods. It is most desirable, and of the greatest national importance, that the old road from Margarito to the Irrawaddi should be reopened and put in decent repair, which has never been its condition since the British owned Assam, though it was well enough kept when the Burmese held the country. The reopening of this road would cost a mere bagatelle in comparison to the results which would accrue, and the amount of trade to be anticipated with western China is utterly incalculable. The inhabitants of the trans-frontier country we have found docile and fairly industrious, and their country has unquestionably great mineral resources."

Mr. White's views above recorded will, we feel sure, prove of interest to the many who recognize in him one of the leading and most enterprizing spirits connected with the great tea industry of India.—*H. & C. Mail.*

EFFECT OF POLARISED LIGHT.—A correspondent of *Nature* attributes the absence of trees in the extreme north of Scotland, the Shetland Isles, &c., in part to the fact that the light in those high latitudes is polarised, and polarised light is well known to be much less intense in its chemical action than ordinary white light.—*Gardeners' Chronicle.*

EFFECT OF PRUNING.—MM. Casocia and Savastano have recently compared the analysis of the juice of pruned and unpruned Vines respectively. The Vines, belonging to nine distinct varieties, occupied 1 hectare of space ($2\frac{1}{2}$ acres); half were pruned, the other half were left intact. On analysing the juice it was found that that produced from the unpruned Vines was the richest in sugar and the least acid. It would be well if similar experiments could be made on Vines grown on the extension system and otherwise.—*Ibid.*

PLANTING IN FIJI.

LEVUKA, March 21st.—Matters have not improved with us during the past month. On the contrary, our continued progress seems to be from bad to worse, and the dread is, that there are depths of depression yet to be sounded before the turning point is reached. The only people all busy seem to be the lawyers and the auctioneers, and their style of business is scarcely conducive to the commercial health of the colony. The general extremity has been their opportunity. Foreclosures and forced sales have provided them with occupation. Bankruptcies have been unpleasantly numerous, and the tone of current rumours indicates the want of confidence in general stability. The effect produced is most disastrous. Real estate, whether improved or not, has no actual realizable market value. Properties mortgaged for a third or fourth their estimated worth three years ago are put up for sale now, and are generally knocked down at the upset represented by mortgage and interest in arrears. In a few instances only has there been a slight advance; and there is now a property of over 18,000 acres advertised for sale to satisfy advance and interest to the amount of £11,800. This consists of seven separate blocks in different parts of the group, some of them being Hewa lands under cane. The greater portion is of first-class quality. Three years ago the owner would have laughed to scorn the man who would have offered him £50,000 for his property. Yet if arrangements are not made to discharge the debt, it is doubtful if, when the sale takes place, there will be a single bid in advance of the sum claimed. The increased cost of labour and the depression in the sugar market is also telling in another direction. The first has caused the expense of bringing enterprizes into working order very considerably to exceed original calculation, and the second has caused return to fall as far short of estimate. The result in one case has been complete stoppage. The company working under the style of Messrs. Sharpe, Fletcher, & Co. has expended on its Navua mill over £100,000. It has been at work for some time, but returns have kept pace with necessary expenditure. More money is required, and this the shareholders are indisposed to put into the venture. The mill has therefore stopped. The hands have been discharged, and only a caretaker has been in possession for some weeks. The managing partner recently left the colony to interview his brother shareholders, and arrange, if possible, for raising more capital. In this he has evidently failed, and today the property is advertized for sale. It is only fair to the colony to say that the enterprize has been recklessly mismanaged from the start.

The census record, which has been published in the native official journal, the *Na Mata*, presents the native chance of survival in anything but a satisfactory light. The general increase for the year treated of was but 33, as compared with 114 for 1882, and 204 for 1881, so that there appears to a steady decadence of vital force. These figures should bring the aggregate of the native populations up to within a fraction of 115,000, but the extract number is not stated. The marriages for the term noted were 1,078, the births 1,425, and the deaths 4 392 It will be noticed that the birth rate, set at 38·47 per mille is a good one, but the death rate, 38·18 per mille, is appalling. More particularly does this appear in the fact that 1,546, or 35·2 per cent of the deaths were those of children under one year old. The deaths among the aged were 1,074, or 24·45 per cent; and in referring to this heavy mortality it is unanimously attributed by the natives themselves to the neglect of the weak children and failing elders. It is reported that the people have been strictly enjoined to "take great care of the sick, and attend to them, and this they say they cannot do." The chiefs also complain that there is a disinclination on the part of the young to marry. "The young women do not marry, but wait till they are old. Also the young men; they take the old women to be their wives, that they may hang about the house and have their work done for them." The general prospect is not an encouraging one as regards the Fijians, and it is feared that in the interval it has become much worse. The Bose resolutions are chiefly noticeable for a prohibition against flogging women, as had been done at Ya awa, and for a recommendation of the chiefs that those "no'er-do-wells" who will not attend to their plantations shall be publicly flogged. His Honour answers to this suggestion, "I concur generally, but will consider further;" and when it is remembered that these "plantations" include not only food gardens, but Government cane cultivations, &c., for the raising of native taxes, the question arises—Is there not something strongly suggestive of slavery in this proposition to publicly flog their tale of work out of the men?" How does this contrast with the labour laws before referred to, and what would be thought of the planters if they dared to make this suggestion, which, in the interest of the Government, is concerned in generally, and will be considered farther by the Administrator?—*Argus*.

PLANTING IN COORG, SOUTH INDIA.

In the last administration report of Coorg, we find the extent of land under food-grains remained stationary. Seventy-three thousand and twenty-one acres have been cultivated with rice, and 1,433 acres with dry crop, or 6 acres less than in the previous year. The most important, although not now the most paying, industry in the province is that of coffee-planting. There are 218 coffee estates owned by European and 44,428 by natives covering a total area of 74,074 acres. The area of the land held by the former is 38,213 acres on an assessment of R69,398, and by the latter 35,861 acres on an assessment of R65,892. Besides these, coffee to a large extent is grown on the *bane* (uplands attached to rice fields), the extent of which is roughly calculated at 13,000 acres. The average size of each coffee plantation held by Europeans is 185 acres and by natives 8 acres. The number of persons resident on European coffee estates and large native estates is 26,893, according to the last census, taken on the 17th February 1881, but this number is augmented by about 20,000 during the picking season which closes in January. Of the whole area of land under coffee cultivation, 41,600 acres are said to be in full bearing. Owing to the heavy crop picked the outturns estimated at 2 cwts. the acre on native, and 4 cwt. on European estates, come to about 5,109 tons, almost the double of the previous year. Calculating the average cost of cultivation at R100 per acre on European estates and R40 on native, each cwt. of coffee cost on an average R23 to produce. The cost of cultivation, at the rates per acre assumed above, comes to nearly twenty-nine lakhs of rupees. Of this not less than 60 per cent may be estimated as having been the price of labor. The value of coffee produced, taking the selling price to be on the average R25 per cwt. on the spot, come to R25,54,000.

An agricultural farm has not yet been established in Coorg, but efforts were made during the year to improve products by the introduction of fresh seed. A fine quality of rice, which was obtained from Alur, has been cultivated by the ryots successfully, and another variety known as the jira, has been obtained from Canara, and will be tried this year.

Unfortunately most of the wheat received from Cawnpore failed to germinate; while that obtained from the adjoining district of Hassan in Mysore, though it gave every promise of success in the Nanjarajpatna Taluk, was damaged completely by two very heavy and altogether unexpected downpours of rain in the month of December, which ruined at the same time the ordinary Bengal-gram crop grown by the ryots.

The potatoes, carrots, Bellary onions, squashes, dillseed, Japan, French and broad beans, supplied to the market gardeners, rotted away in most taluks from the same cause, and partly from want of care, but they succeeded fairly in others. Their cultivation was introduced from Hassan, where they were first raised several years ago from seed distributed by the present Commissioner of Coorg.

Tobacco seed from Dindigul and Coimbatore, of the variety from which Trichinopoly cheroots are made, succeeded in the Nanjarajpatna and Yelsavirshime taluks.

A good variety of ginger introduced from Shernad in Malabar is thriving well in most taluks. The introduction of the pepper vine from Malabar proved a failure from the cuttings having rotted in transit.

For the first time for several years past, the planter experienced great difficulty in procuring a sufficiency of labor for plantation work. The Mysore coolies were late in coming in, and, when the batches did arrive, they were less than half the number for whom advances had been made. The causes assigned were the abundance of the crops which had caused a fall in prices of food grains, and the demand for labour on the Bangalore-Tumkoor line of Railway which was under construction. Some of the estates suffered from the weeds not having been removed in time, while in other cases the managers and proprietors were saved from heavy loss only by the strenuous efforts which they made to import labour from the Tamil country near Salem, and by employing the costly but valuable labour from the Western Coast. Owing probably, to questions affecting the tenure of land in Malabar, the numbers of coolies, chiefly Moplas, who were attracted from that part of the country, were unusually large, and with their aid the difficulty of securing the crop was tided over. Many of the Tamil coolies, who were imported, failed to give satisfaction, but others have done well, and their advent to the country is welcomed, the more so as many of them are willing to engage without advances. The Mopla labourers proved also most useful in doing good work on petty contract on the roads.

To compensate, as it were, for the losses in the previous years, the number of deaths among cattle was comparatively light, being 2,668 head against 14,347 in 1882-83; and this notwithstanding that the rainfall was fully up to the average. Evidently, nearly all the weakly cattle had succumbed to the heavy monsoon of the year before.

No greater blow has been dealt for many years past to the prosperity of Coorg, and to the coffee interest, to which it owes its flourishing condition, than the heavy fall in the market price, which took place at the close of the season. It has decreased from R40 to R25 the cwt. within the last two years, and in the home market from 100 shillings to 61 shillings, or 40 per cent. The cause is attributable to the overstocked condition of the London market. The *Times'* in a recent issue describes the stock as apparently inexhaustible, and states that it is not known to how low prices may still fall. Ceylon and Coorg have to compete with Brazil where there is slave labour, and where fresh land is said to be abundant. The extension of railway communications in Brazil is another advantage in favor of that country, and in recent years the planters there have been taught by settlers from Ceylon the proper manner of curing and preparing coffee, so that Brazil coffee has lately obtained in the home market as good a price as that of Coorg. The native coffee is chiefly in request for the French market, to which quantities have been exported direct from the Western Coast.

Owing to the good crops reaped in Mysore, the prices of food grains showed a tendency to fall still lower. Rice, the staple crop of Coorg, fell to R1-12-0 the maund of 80 lb., or annas 12 less than in the previous year, and ragi to R1-2-0 or annass 5 less. The market was so dull at the end of the harvest in the Yelsavirshime taluk, that sales could not be effected for some time. The ryots acknowledged the liberality of Government in giving them time to effect a sale by the recent alteration in the payment of instalments of revenue.

The rain-fall during the year was slightly above the average :—

	Inches.	Cents.
That registered in Mercara being	140	29
" in South Coorg	80	35
" in East Coorg ...	14	33
" on the Western Ghauts	252	79

The season opened very favorably for all agricultural operations. The timely blossom showers led to fine crops of coffee and cardamoms being picked. The subsequent rains ensured the safety of the rice crop, which was fully up to the average, but in Eastern Coorg serious damage was done by the heavy rains to the ragi and Bengal gram crops, especially by two unexpected downpours, which took place in the month of December. These showers caused also some damage to the coffee crop when drying on the barbacues, and to the rice crop in South Coorg.—*Indian Agriculturist.*

MAURITIUS ACCLIMATION SOCIETY.

Meeting of Friday, 27th March 1885.

A communication from Mr. P. Lemiere was read on the Jarrah tree of Australia.

The President announced that he had received a letter from Professor Heckel, of the faculty of medicine and science and *Directeur du Jardin de Marseille* who had just terminated an important work on the Kola, a tree which contains a very large proportion of *Cafeine*. In his last letter, he announces that he will send the Society a lot of fresh seeds of the Kola, which was a tree destined to render great service to the colony.

The President spoke of the Donodaké, *Sarcocephalus esculantius*, a tree which is common on the West coast of Africa and has febrifuge properties equal or superior to that of Peruvian bark; also of a great Coffee tree, native of Mayotte and the Comoro islands, which produces excellent small grained coffee. Some seeds had already been sent to Mr. Potier, the Directeur du Jardin Botanique at Réunion; also Cassia seeds which produce astonishing results as a febrifuge, but which were nothing else than Cassepuante; the letter said they were much more effective than Peruvian bark. The whole of the plant was febrifuge, except the root which was diuretic. He found in the transactions of the Royal Society for 1865 that the *Café d' Afrique* had been recognized to be cassepuante.

The President called the attention of the members to the cultivation of the Illipé, a tree which grows very well in Mauritius. This tree furnishes the soap received from the Ceromandel Coast. Its seeds furnish a kind of oil or rather butter. The blossoms which appear in December and January contain 60 per cent of sugar. In India a great deal of alcohol is made from them. In France the flowers are mixed with the grapes in the manufacture of wine. Each tree produces 400 lb. of flowers, which are worth 250 francs a ton at Marseilles.

The President called attention to the culture of the Ylang Ylang; he had planted a cutting 8 inches long which bore flowers in one year, the flower has a strong perfume and resembles *champac*, or the flowers of the cœur-de-bœuf. The flowers were worth 750 francs the kilo. [*Credat !*—ED.]

The President remarked that Mauritius produced a great many useful flowers which were lost. It was very easy to make essence of geranium by steeping the leaves in water, and then distilling it, the essence which was lighter than the water was easily distilled.

The President announced that he had received from Mr. Pelte for Mr. Liénard some Copal plants.

A distribution was made of Malta orange trees.

FIBRE EXTRACTION.—A Dutch artisan named Plaisier claims to have invented a hand-machine for fibre extraction. It separates all the woody parts and leaves from green ramch, and turns out the fibres clean without damage and free from gum. The samples of fibre produced by the machine are said to have been reported upon favourably.—*Pioneer.*

THE WEATHER AND CROPS UPCOUNTRY.
TRIAL OF JACKSON'S NEW TEA DRIER.
THE NANUOYA RAILWAY.
THE HAPUTALE EXTENSION.

GAMPOLA, May 2.

Splendid appearauce of crop on the coffee on some estates in Udapussellawa. Crops in Dimbula likely to be very variable : some estates having good prospects, while others close by are very poor. A continuance of this weather for a week or two will give the Agras a considerable addition to its crop.

The Nannoya section opens on contract day.

The trial of Jackson's tea drier takes place at Carolina today, Messrs. Walker and Rae being present. A report of the result will follow by telegraph.

Mr. Waring is busy on the Haputalo estimates.

JACKSON'S VICTORIA DRIER.

DIKOYA, May 2.

Jackson's new drier, the "Victoria," Class B, now at work on Carolina, gave most satisfactory results—160 to 180 lb. dry tea per hour. It is self-acting throughout. The flavor of the tea is improved, and the bloom retained on account of not being handled.

EX-CEYLON PLANTERS: NOTES FROM "OLD COLONIST."

North of the Tweed, April 8th, 1885.

Another old Ceylon planter has just favoured me with a call : John Ross—at one time with R. B. T. on Ambecotta, afterwards in Rakwana, finishing up his planting career in Upper Dimbula, where he who "knows best" will acknowledge John did some excellent work. For the past hour we have been busily engaged in taking the Pioneers of Dimbula to pieces and putting them together again. Mr. Ross's career since leaving Ceylon —some fifteen years ago—has been a most varied one, for some time in Mauritius and ultimately in South Africa, during the Zulu war attaching himself to the transport service, where he was killed—(according to a correspondent of the *Observer* at the time !) Now we find him digging diamonds, now farming, now a gold digger—finally settling down at the more congenial work of *nurseryman*, a business which his early training makes him peculiarly well fitted for. He has already introduced many tropical and sub-tropical trees from India, Mauritius and Australia : oranges, mangoes, figs grow luxuriantly, cinchona fairly, while whole forests of the beautiful *Grevillea robusta* have been distributed over the country. Thus, our quondam friend the coffee planter is proving a *bona fide* benefactor to a country so sparsely wooded as South Africa, while, at the same time I am glad to understand, he is laying the foundation of a substantisl and very lucrative business. Old Ceylon friends interested in the acclimatization of trees might do worse than communicate with Mr John Ross, the Cedars, Town Bush Valley, Maritzburg, Natal.

THE FORBIDDEN FRUIT.—It is thonght in Peru that they will before long be able to ship to the United State the far-famed fruit known as the chirimoya, a species of custard apple, which the Peruvians declare to be the most delicious product of nature. A theologian in Lima once expressed the opinion that the chirimoya must have been the forbidden fruit of the Garden of Eden, and he did not wonder, therefore, that Adam and Eve were tempted to eat it.—*American Grocer.*

THE CHEMISTRY OF TEA.—The general idea of preparing tea leaves for the market is that they are carefully picked from the bushes, then dried, and finally packed in the condition in which Western nations receive them. In their annual report on the Indian tea trade, Messrs. George White & Co. show that a good deal more has to be done, and that on the proper doing of it largely depends the quality of the article. Withering, fermenting, firing, and rolling, are some of the processes which the modern planter ought to understand. But such knowlege is difficult to come at, being only acquired, as a rule, by long and very often costly experience. It is, therefore, suggested that the tea associations of London should subscribe a fund for the prosecution of chemical experiments, with a view to determine the best and safest processes. In Ceylon, where the planters were especially enterprising, this object is partly attained by the interchange of ideas through the medium of the local Press, and there seems little doubt that the superiority of Ceylon tea is due in some measure to this good fellowship. Messrs. White describe the method of manufacture as "cooking," and to entrust it to unskilled hands involves the same disastrous consequences as result when the raw materials for a dainty repast are operated upon by a kitchen maid. Considering that the yield of our Indian and Ceylon plantations during the present year is estimated at nearly seventy million pounds there ought to be no difficulty in obtaining the comparatatively small sum required for the proposed experiments.—*Globe*, March 28th.

COCONUT TREES IN FORTIFICATIONS.—At a time when we hear of coconut trees being cut down to allow of free play for the heavy guns to be mounted on Mutwal Point near Rock House, it is interesting to recall a passage like the following from an old number of the *Philosophical Magazine*, and which has been reprinted in our compilation on the Coco Palm, positively now about to be closed. Military men especially ought to be interested in what is said of the use of the tree in fortifications :—The stem of the coco palm is composed of the strong ligneous fibres, crossing each other like net-work it is not sufficiently hard and compact to be used as timber ; but it is extremely elastic during the time it vegetates or retains its sap. M. Le Goux de Flaix states, that it has then such elasticity as to cause a cannon-ball to rebound and be deflected from it. In corroboration he relates that, " a military officer in the service of the French East India Company, who in the year 1760 commanded Fort Alempane, the revetments of which could not have sustained ten cannon-shot, endured a siege of ten or twelve days ; because M. Verri, who had the command there, conceived the idea of causing the facings of the walls to be covered with coco nut trees, suspended from them. Another proof of my assertion in regard to the astonishing elasticity of the wood of the coconut tree occurred during the memorable siege of Pondicherry, in 1778 : a ball fired from the place accidentally struck a coconut tree in an avenue opposite to it and perforated the body of the tree, which bent and suffered it to pass through it, as if it had gone through a mattress. The trunk then closed up, bringing together all the ligneous needles of which it was composed ; and at the time the place surrendered, the wound was perfectly healed. I mention these facts, that advantage may be taken of them, should urgent circumstances render temporary fortifications necessary in a country where coconut trees can be readily obtained. I was sensible of the utility of it during the siege of Pondicherry in 1778, at which time I caused the merlons of the ramparts to be covered with it."—With abundance of cahook for earthworks and coco palms, Colombo is well off for means of defence in some respects.

BIRDSNEST collecting at Gormanton is in full progress, and a fairly large crop is being obtained, but owing to the low prices now ruling for nests, principally in consequence of the war in China, the value of the total outturn will be below the average. —*North Borneo Herald.*

ORANGES IN FRANCE.—The taste for oranges seems to be as decidedly on the increase in France as the taste for tea. Fifty years ago the annual consumption of oranges in the country barely reached 15,000,000 lb. weight of the fruit. It had risen to double that quantity in 1856, to over 50,000,000 lb. in 1866, and last year over 100,000,000 lb. of oranges were imported. At one time Spain was almost the sole source of supply; but both Italy and Algeria now send their quota of the fruit to the French market, the Algerian contribution being by far the larger of the two. The exportation of oranges from the colonies to the mother-country, which only amounted to 16,000 lb. in 1836, attained the large total of 10,000,000 lb. in 1884.—*Pioneer.*

AMONG the various samples of Borneo produce which Captain R. D. Beeston has sent to Melbourne per the barque "Ellen" is one of the vegetable tallow or vegetable wax (minyak tungkawaw) which is stated on good authority to be the best lubricant for machinery that can be procured, and which combines economy with efficiency. There is no doubt but that this product if properly attended to will command a high price and be received with high favour in the Australian colonies, as while it is as good as palm oil, its price will never run to anything like so high as that commodity. Captain Beeston thinks very highly of it, and has particularly requested his Melbourne friends to have it thoroughly tested. We shall be happy to hear the result of the experiment.—*North Borneo Herald.*

CEYLON TEA AT HIGH ALTITUDE.—Upper Abbotsford, Lindula, 23rd April.—I have the pleasure to send you the result of our last two weeks' picking up here. You will note that the income was according to the flush and the field—one day an average of 27 lb. and another day only 12 lb. per cooly. This year we allow our flush to run from 10 to 14 days, instead of from 7 to 10 days as last year. Beyond 14 days we cannot well leave it, not only because it might harden, but because the tip and pekoe leaf get pierced by some insect against which I have not yet been able to obtain a writ of "Habeas Corpus." It certainly is not the solitary specimen of *Helopeltis* that I discovered *last year* that does the harm, for Dr. Trimen never returned me its mangled remains. The enemies, I suspect, are a fishy-looking insect with a crest like a woodpecker and a crocodile's tail, and a minute fly with spotted transparent wings. I must send specimens to those learned in insect lore for identification.

15th ...	1	12	12	
16th ...	124	1,700	13·62	
17th ...	132	2,772	21	
	365	6,076	16·64	

My average per cooly up to date this year is 20·08 lb. The excess over last year is already 12,933 lb.

"NEW COMMERCIAL PLANTS AND DRUGS."—Mr. Thomas Christy sends us No. 8 of this publication, containing accounts of the following:—New Plants.—Kola Nut (with coloured plate), its Uses and Cultivation; Fermentation of Produce; Gutta Perchas; New Solanums, illustrated; Sorghum Sugar; Nutmeg Genus, being a description of known species, illustrated; etc., etc. New Drugs.—The Cuca, Cucain—its uses and results obtained; Hydrocotyle Asiatica; Papaine: Cuprea Barks; Cinchonamine, and many other new drugs.—Reports on Produce Examined, &c.

INDIAN EXPORTS OF GOLD.—We have from time to time given particulars of the exports of gold from Madras—the output of the mines in Colar. The following figures giving the exports since June last may be of interest:—

	lb.	R.
June	2½	... 2,100
July	—	... nil
August	—	... nil
September ...	14½	... 21,700
October	34	... 1,60,000
	oz.	
November ...	1,434	... 37,400
December	—	... nil
January	239	... 11,000
February... ...	—	... 12,120
March	245	... 11,400

—*Madras Standard.*

FACILITIES FOR BOTANICAL RESEARCH.—An article with the above heading, in *Nature* of 19th March, points out to students the wisdom of visiting tropical and other gardens such as that at Buitenzorg in Java, the Director of which, Dr. Treub, has issued a circular on this subject. After referring to the Buitenzorg garden, the writer says:—

These facilities for botanical research in a tropical climate, thus offered freely to strangers by the Dutch, naturally suggest to the English mind that with all our colonies we have at present little of a like nature to offer: we have in our gardens at Calcutta and Peradeniya as good chances of establishing laboratories for botanical research as the Dutch had at Buitenzorg. Prof. Haeckel's interesting account of his recent tour in Ceylon, and of his visit to Peradeniya, gives some idea of the scope there would be for a young botanist to carry on morphological and anatomical work. In the sphere of thallophytic botany Mr. H. M. Ward has already shown that a lengthened stay in the tropics may lead to the attainment of very valuable results.

GREEN BUGS AND COFFEE.—From Haputale, the Hon. R. D. Downall writes:—"Just reading a letter in the *Observer* 'From the Hills,' I came across the passage 'when leaf fungus and scale insect are absent.' By parcel post I send you a few green bugs, and should be glad to know if this is the 'scale insect' referred to? I also send you in same box some coffee cherries which I firmly believe are attacked by this pest (you will observe the marks on the outside, and the lightness of the parchment inside), and the outturn of the parchment is rendered light and inferior from this cause. This bug is well-known by Tamils as the 'narvala poochie'; it often attacks fields of grain on the Coast, and, when it does so, the fields are abandoned for the season, as the beans or gram and other grain grown, become light and inferior like the coffee here. I have made many enquiries, but cannot learn that the attacks of this pest have been noticed. I have sent the insects to Messrs. Trimen and Green: the former did not appear to attach any importance to their presence; to the latter gentleman I have now sent some cherries. I attach importance to their presence from very unpleasant *facts*, which are as follows:—Since their appearance here in numbers, only this year 1884-85, the outturn of first parchment from the cherry which used to be 70 per cent has fallen to 59 per cent and 60 per cent; and that from fine vigorous coffee which has *never* suffered to any extent from leaf-disease, and has had no attack for 18 months, the coffee is bearing a *good* crop, and bearing it *well*. There is also this fact

that on Maha Uva (Lower Maturata) where the coffee has suffered *terribly* and *recently* from leaf-disease, and the trees are much punished therefrom, and from a really *heavy* crop the outturn is 6 per cent better than here: the sample has hitherto always been inferior and the outturn worse, but *there* the bug is *not*. I should feel much obliged if you would let me know if the insect and its ravages have come under your notice before? The Tamils also say that it sucks the sap from young wood, and so prevents its bearing." Of course, the 'scale insect' referred to in the letter "From the Hills" was the coccus and not this green bug. Mr. S. Green writes to us:—"I have written to Mr. Downall for further information. The scale insect is a coccus, while the bug belongs to quite a different family, and is even placed by some entomologists in another order. It is not the green bug so unfavorably known in Colombo, being more yellow than green and spotted with brown marks. It however belongs to the same family. Mr. Downall has also sent with the bug a few specimens of the beautiful green weevil, described in Nietner's 'Enemies of the Coffee Tree,' No. 26, page 19 of the new edition. It is covered with iridescent green scales. Perhaps Mr. Downall calls this a scale insect."

THE TAXING OF TEA IN CHINA.—That the conduct of the hostilities with France in Tonquin and Formosa should severely tax the finances of the Chinese Government and sooner or later compel them to resort to extraordinary means for increasing the revenue was only to be expected. It is proposed to increase taxation on tea, opium, salt, accumulation of foreshores (*lit.* "sand-fields"), and wine and tobacco shops. Of these propositions the one that will most nearly concern foreigners engaged in trade with China is the one for increasing the duty on tea. The *Hu Pau* says that "the alternative proposals for taxing tea are (1) to levy a tax of 3 mace per five catties at the place of export; (2) to levy 3 taels 9 mace per hundred catties, in addition to the barrier dues; (3) to levy the foregoing, but to allow the barrier fees to be commuted by a first double payment. This does not affect the Customs export or frontier dues. The Empress approves provisionally, but the details are to be referred to the provincial authorities." The least of these alternative taxes would, on a rough calculation, be not less than 2d. per lb. on all qualities, a huge increase on the common grades of tea, which are most in demand in the English market. No differential duty is imposed on tea in the United Kingdom; whether it comes from China, India, or Ceylon, it pays the same tax. Hence China tea can compete with the Indian and Ceylon product on equal terms, and secures a market. What would happen, however, if the Chinese tea had to pay a heavier duty before export; Even under present conditions it is being gradually undermined by the Indian and Ceylon teas, owing to the superior cultivation and preparation of the latter. With increased duties levied at home, China teas would simply become unsaleable in the English market in a few years. Nor is this all. The business in tea is the backbone of foreign trade in China; its ruin would mean the decay of trade generally, and the loss of fully half the revenue derived through the Imperial Maritime Customs. We say nothing of the reduction of British trade, for that would probably only change its field from China to India, but the damage to China would be great and irreparable. The Chinese Government instead of thinking how they can raise the duty on tea, should—*malgré* their present financial difficulties—rather consider whether it is not expedient to reduce that duty. They have to face the fact that every year the export of Chinese tea to England, its principal market, declines, while that from India grows steadily and rapidly. Ceylon is also fast becoming a rival as a producer of tea, and it is reported that tea of the finest quality can be grown in Natal. There is every reason to believe that it will also soon be cultivated in Borneo and probably in Burmah. It will be difficult enough for China tea to hold its own against its rivals even if competing on equal terms, but hampered by an extra duty of something like 2d. in the pound, this will become impossible. Moreover the Peking Government will, as our Shanghai contemporary points out in the course of an article on the subject, run the serious risk of causing disaffection among the tea-growers if, as is most probable, their produce becomes unsaleable in the chief market of the world. The mandarins will consult their own interests equally with the interests of their country in rejecting any proposal to increase the tax on an article of export the trade in which cannot survive such an impost many years, and would, by restricted consumption, speedily show signs of approaching extinction.—*Daily Press.*

REFERRING to the letter from Mr. H. Shuck, of Larut Lapas Plantation, Island of Sooloo, which appeared in our issue of 28th March, regarding a disease which has appeared in cocoa trees, we are informed by Mr. Shuck that he has forwarded to Mr. Hullett, Principal of Raffles Institution, specimens of both the grub and the beetle to which he attributes the disease in question. The specimens, we understand, will be placed in the Museum, so that planters and others interested in the matter, may have an opportunity of inspecting them.—*Straits Times.*

TEA AT A HIGH ALTITUDE IN CEYLON.—Upper Abbotsford, Lindula, 1st May.—The following is my picking for last week:—

Date.	Pluckers.	Green Leaf.	Aver. lb. per cooly.
April 20th ...	105	2,812	26·78
,, 21st ...	114	2,944	25·82
,, 22nd ...	75	1,348	18
,, 23rd ...	52	784	15
,, 24th ...	18	288	16
	364	8,176	22·46

Average for the year up to date of lb. green leaf per cooly 20·20. Average rate per acre for the 110 acres (deducting 5,286 lb. for young tea), 887·64 lb. The total rainfall for April is 2·72 inches, which fell on ten days. This makes the total for four months of this year 8·40 inches, against 8·79 last year. Today it is very close and cloudy.

TEA IN RUSSIA.—The Russian Ministry of Finance has published some statements respecting Russian trade with China, with special reference to the advance of the duty on tea. It is stated that in settlement of the balance of trade Russia has paid to China in the course of twelve years not less than 130,000,000 roubles (say 13,000,000*l*.), and that the Chinese consumption of Russian productions, especially manufactures and the materials for manufactures, has not only not increased, but has declined in a marked manner. The reduction of the Russian duty on tea, with a view to the encouragement of Siberian trade, cost the Imperial revenues during the period from 1878 to 1883, on the average, 4,500 000 roubles per annum, without giving any apparent stimulus to direct trade. Regret is expressed that the Russian tea merchants keep entirely aloof from the trade in Russian manufactures. During the course of eleven years the exports to Russia from China have more than doubled, the declared value having risen from 9,200,000 roubles to 19,700,000 roubles per annum. The tea merchants concern themselves merely with the profitable satisfaction of the demand of consumers, and this demand is continually expanding, especially amongst the lower classes. They make no efforts to introduce Russian goods to the Chinese but pay for the tea with silver, and frequently with gold. It is urged that this is due to the want of organization amongst Russian traders, each of whom pursues his own personal gain regardless of the general interests of Russian trade and economy, and that it is important that no effort should be spared to promote the consumption of Russian goods in China.—*Indian Planters' Gazette*, 21st April.

PLANTING IN NETHERLANDS INDIA.

(Translated for the "Straits Times.")

By last advices the sugar cane disease known by the name of *Sereh* is steadily spreading from West to East Java, the only means of checking its progress being to pull up and burn the diseased canes. Scientific inquiry has hitherto failed to find out the nature of the disease and has resulted so far in guesswork at its causes, as is evident from a lengthy report by Dr. Treub, a Government botanist, who had been officially charged with carrying on researches on the subject, specimens of diseased canes being sent to him for examination and experiment. Among their roots he found an animal parasite which was most numerous on the most diseased plants, but was altogether absent from the roots of healthy canes, and turned out to be a *Heterodera* of the same kind, but much smaller, as the parasite which in Europe has proved to be the cause of that degeneration in beetroots ascribed at first to exhaustion of the soil. This parasite called by Dr. Treub *Heterodera Javanica* might with almost absolute certainty be designated as the cause of the *Sereh* disease, were it not that in specimens of diseased cane preserved in spirits, and other specimens received afterwards at Buitenzorg, *Heterodera Javanica* was sought for in vain which may be accounted for by the roots of the latter specimens being too short, from the extreme ends more likely to be parasite infested having been broken off. Dr. Treub comes to the conclusion that even when it has been conclusively made out what parasite brings on the disease, there will be necessary not less difficult researches into the habits, propagation, and spread of this microscopic creature, before anything can be recommended with certainty as remedy for the disease. In any case further inquiries will take months.

CULTIVATION OF TEA, CINCHONA, &c., IN MALABAR, SOUTH INDIA.

(To the Editor of the "Field.")

SIR,—In your issue of the 21st instant, I notice a letter from Mr. A. R. Hinde, anent the culture of various promising products suitable to the Malabar and Wynaad districts of Southern India, and this being a subject of great interest and importance, perhaps the following additional details and estimates may prove of value to some of your numerous readers.

I have already given you my views regarding Rheea Fibre cultivation, together with full estimates for bringing 1,000 acres into bearing; consequently, any further remark regarding this valuable product would be superfluous, beyond my endorsing Mr. Hinde's opinion that rheea cultivation must pay on the fertile lands in the Malabar and Wynaad districts, particularly those lands situated immediately on the slopes of the Western Ghauts.

Regarding TEA. On the higher portions of the Nilgiri Hills and in the Wynaad, 400 lb. of tea per acre per annum is looked upon as an excellent return; but I think the time has now arrived when the South Indian planters should take the initiative from those of Ceylon, and plant at lower elevations than they have hitherto attempted. Taking into consideration the fact that some of the Ceylon tea estates have yielded from 800 lb. to 1,000 lb., and even so high as 1,200 lb. per acre per annum, Malabar and Wynaad, with superior soil, facilities for manure, a cheaper and more constant labour supply, to say nothing of the forcing climate, should compare favourably with Ceylon, even to the extent of exceeding these excellent results.

According to Ceylon estimates, the up-keep charges are put at 45 rupees per acre, exclusive of manuring; but, as I have advocated the system of liberal manuring, almost from the commencement, I have placed the up-keep charges at 80 rupees per acre, and assuming these figures the cost of a pound of tea, should be as follows:—

	400 lb. per acre. an. pi.	600 lb. per acre. an. pi.	800 lb. per acre an. pi.
Cultivation... ...	3 3	2 2	1 7
Crop charges ...	1 6	1 6	1 6
Transport, packing, and shipping... ...	0 2	0 2	0 2
Cost per lb. free on board	4 11	3 10	3 3

The London charges, including freight, amount to 4½d per lb., which gives the gross cost as follows:—

	400 lb. s. d.	600 lb. s. d.	800 lb. s. d.
London charges inclusive	0 4½	0 4½	0 4½
Indian charges as above:—			
4an. 11pi. at 1s 8d. exchange... ...	0 6	—	—
3an. 10pi. at „	—	0 5	—
3an. 3pi. at „	—	—	0 4
	0 10½	0 9½	0 8½

Valuing the tea at only 1s per lb., the following table will give results:—

Yield per acre.	Profit per lb.	Profit per acre. £ s. d.	Profit per 100 acres. £ s. d.	Interest on capital.
400 lb.	1½	2 10 0	250 0 0	about 11½ per ct.
600 lb.	2¼	6 5 0	625 0 0	„ 29 „
800 lb.	3½	11 13 4	1,168 0 0	„ 55 „

CEARA RUBBER.—This valuable quick-growing rubber tree has long since been acclimatized in India and Ceylon, and now its systematic culture in permanent plantations is all that is required to insure success from a commercial point of view. It has been found to thrive admirably when planted in rows about 12ft. apart, allowing about 300 trees to the acre, planted at this distance. After the fifth or sixth year the following should be the lowest returns, provided the trees are carefully tapped:—

	£ s. d.
Sixth year, 300 lb. rubber per acre, value, say 3s per lb...	45 0 0
Deduct cost of up-keep, supervision, &c., per acre	8 0 0
Profit per acre...	37 0 0

Or, £3,700 per 100 acres after the sixth year.

When it is observed that the above is irrespective of any other crop, such as rheea or coffee, which might well be cultivated under the shade between the rows, it will be seen that there is ample scope to enhance the value of the returns per acre.

CINCHONA.—The cultivation of cinchona in Wynaad has been attended with considerable success of late, but much remains to be done, especially in the matter of planting those superior kinds, the barks of which are known to be superior in yield of quinine. I am in possession of recent advice from the estate of a friend of mine in Wynaad to the effect that the average results of twenty-one trees not quite six years of age has proved on chemical analysis, to be 11·31 crystallized sulphate of quinine, which result, at the present market rate of ten pence per unit, represents the value of the bark at over 9s per lb. These trees are of the Ledgeriana species, and all information up to date indicates a most promising yield for success to cultivators of Cinchona Ledgeriana in Wynaad. Planting this valuable species on semi-abandoned coffee estates, or on exposed land, has been, and will be a failure; and from this reason alone C. Ledgeriana has acquired the reputation of being a delicate species; but on well sheltered and moderately rich virgin forest land, or even planted amongst coffee, it ought to be cultivated very successfully.

I feel I cannot trespass further on your valuable space by entering into any more detailed estimates, but I shall be happy to forward them to any gentleman who may feel interested in cinchona. Land in S. India has not been so cheap for years, and in some instances I have known well-roaded estates over 1,000 acres in extent, containing considerable areas of good forest and scrub land, including well-built bungalow and estate buildings, sell for such small sums as £2,000 and £3,000.—W. J. KEMP.—*Field.*

THE BRAZIL COFFEE CROP.

That there has been an error in the estimate of the present coffee crop can now hardly be doubted. The receipts from July 1st to 28th February were 3,015,000 bags and the present scale of receipts shows plainly that the interior is far from bare of coffee. The want of attention to this matter of crop estimates becomes every year of greater importance; not only from the point of view taken by the merchants interested in the trade, but also because as the article furnishes the basis for the greater part of our exchange operations, the more or less accurate crop estimate becomes a feature in the finances of the empire. We had occasion to treat of this matter, and from the best information we could gather the crop was estimated at not over 3,500,000 bags, but if 3,000,000 bags be received in eight months and receipts are averaging over 10,000 bags per day, of which the railway is contributing a very large proportion, it seems proved that the experters have again been misled by the planters. That the result will be, if it is not already, a further loss of confidence in all Brazilian coffee crop estimates; we do not pretend to deny the great extent of the territory planted with the bean further complicates the business; but it would almost seem that a systematic course of misrepresentation is pursued by planters and their agents, to the end of availing of some momentary advantages, assurely followed by distrust and loss. The true interest of the planter leads to the furnishing of the very best information as to the coffee crop, for upon it depends to a most important degree his own credit; yet it is not infrequent to hear that they individually have good to fair crops, but that their neighbours will gather little or nothing! What reliance can possibly be placed in the reports of such doubtful witnesses? No export house in Rio should pay the least attention to the reports as to crops, but should mistrust every estimate that comes from parties who seem to take the greatest interest in misinforming their customers. It is true that farmers, as a rule, underestimate their crops, without reflecting that they may thereby seriously injure their own credit: but in the case of the Rio coffee crop both public and commercial credit are involved, and the sooner some reliable system of reports as to the crop is organized, the better it will be for all concerned.—*Rio News.*

ERYTHROXYLON COCA LEAVES.

Information regarding the preparation for commercial purposes, communicated to the Madras Board of Revenue, by M. A. Lawson, Esq., Director of Government Cinchona Plantations, Parks and Gardens, Nilgiris, consists of the extract on the subject taken from Bentley and Trimen's medicinal plants, which we have already given in the *Tropical Agriculturist*. Mr. Lawson adds:—From the above extract it will be seen that the chief points to be attended to are—

1st.—The rapid drying in thin layers of such leave as are fully developed and are yet not too old.

2ndly.—The immediate packing of the dried leaves in air-tight boxes.

3rdly. Those who possess and desire to harvest leaves for sale in England should experiment on small quanties in different ways until they arrive at a satisfactory result, and to this end I would recommend them to proceed as follows:—

(1) Pick the leaves early in the morning.

(2) Spread the leaves out on some smooth surface, such as boards, so that there should be—(*a*) One layer of leaves. (*b*) Two layers of leaves. (*c*) Three layers or thereabouts of leaves.

(3) Select a place for drying the leaves which is exposed to the sun, and if the leaves curl up or turn brown, try different degrees of shading.

(4) Pack the leaves tightly as soon as dried in layers in tin or other air-tight boxes.

Mr. Hooper experimented upon a sample of leaves from plants grown at Burliyár; from these he extracted a 2 per cent crude alkaloid. Some of this was given to Dr. Bidie who handed it over to Dr. Bruckman for trial, and Dr. Brockman has pronounced the compound to be worthless. From this, however, nothing more necessarily follows than that the leaves were improperly selected or improperly dried, or that the necessary chemical processes in extracting the alkaloid were not observed.

Mr. Hooper will be shortly engaged upon fresh experiments, and when these are completed, they shall be communicated to you.

COL. MONEY'S LETTERS ON TEA: NO. II.

East India Club, St. James' Square, London, S. W.,
27th March 1885.

I have just sent the following to the London *Times* on the proposed enhancement of 3d per pound to the Duty on Tea, which, sad to state, The *Times* advocates:—

"Sir,—It is proposed I hear to increase the Duty on Tea from 6d to 9d per pound. *Why* tea, a necessity for the poor, and a harmless drink, should be taxed at such an absurdly high rate, it is difficult to perceive. If this increase is carried out it means 100 per cent on Chinese, and 75 per cent on Indian teas, *i.e.*, on the prices they now fetch in Mincing Lane.

"The increased tax, like the 6d hitherto, will all be paid by the consumer, *not* the retailer, who, considering the enormous profits he makes, could well afford it. Is it fair, with the distress prevailing today, thus to tax the very poor by simply doubling the cost of what is almost necessary to their existence? The 6d duty is already out of all proportion to the value of the article. Some Chinese tea sells 6d per lb and pays 6d duty!"

Whether they will insert it is a question, but, if they do not, I shall get it into some other papers. It is perhaps not likely the letter will do much good; still I shall feel more satisfied having done my little all to stop it. Is there any article on which such a heavy duty is levied as tea? I know of none except cigars, and, they being a luxury, the tax is legitimate. What would be thought on a proposed tax on bread today? But is not tea, after bread, one of the necessaries of life, and perhaps the only solace with his tobacco the poor man has. What a crying shame to place an *ad valorem* duty of near 100 per cent on such an article!

How, if done, will it affect the producer? Supply remaining equal, and demand diminished owing to the extra cost, lower prices in the market are (at least so it seems to me) sure to follow. Yet there are some here who deny that increased duty will necessitate lower prices. I presume they do so on the supposition that supplies will in a measure fall off, as the cheapest Chinese teas *cannot* bear a 9-penny duty, and that increase of population will to some extent create the same demand.

But the study of Tea Statistics shows there are many, elements to consider if one tries in any way to look ahead. As far as I can judge, the increased duty of 3d, if it is carried out, *will* necessitate lower prices, which yet may not be lower than those quoted today, only lower than what would have held in the future had it not been done.

The fact is, that, looking at the tea figures of the last few months, and the future as far as one dare to cast it, it appears that what we have all longed-for so long has at last taken place. Demand has overtaken supply. The aggregate stocks at the beginning of this month stood in round numbers at 101 million pounds, as against 116 million and 111 million in same month of 1884 and 1883. This is, of course, due to the large monthly deliveries which have ruled lately, and, supposing them to continue (that is not checked by this woeful contemplated increase of duty), the probability is, that, on July 1st next, the stock in hand will not much exceed 40 millions, or about 2½ months' supply. Were England not engaged in foolish wars, so that a revival of trade and prosperity might be looked for, this would indeed be good news

to the planters of India and Ceylon. As it is however, with extra taxation imminent, the tea duty raised and consequent diminished deliveries, no great rise in prices is likely. Had it been otherwise, the year 1885 would have been probably a bright one for the Indian and Ceylon planters, and even as it is, if the worst comes to the worst, I doubt prices being any lower than theyare now.

The Russian tea duty has been raised from 73 to 93 copecks, *i. e.*, equivalent from 1s 5d to 1s 9d per lb., but I see not how this can, in any sensible way, affect our market.

But "on dit" that, like ourselves, wanting money for war purposes, the Chinese are about to increase the export duty on tea, making it equal to 4¾d instead of 3½d. This is a very serious increase, about 36 per cent, and would make it harder than ever for the Chinese to sell here at present prices. Should it be done, Chinese imports, I think, must decrease somewhat, and Indian increase correspondingly.

The population of and the total consumption of tea in the United Kingdom, the consumption per head, and prices of tea in bond in past years, are all factors when trying to look ahead. Some of these figures will interest your readers. I have lately been thinking of collecting them for, say, the last 30 years, and arranging them in a tabular and readable form. When I do so, I will, of course, send it to you. The disjointed information below is the first step.

Thirty years ago, population in the United Kingdom was 28 millions. Total tea consumed 63½ million pounds. Consumption per head, say 2¼ lb. Price in bond 1s 3d. Duty 1s 9d.

Six years back (1878), population was over 35 millions. Total consumption 158½ millions. Consumption per head 4½ lb. Price in bond 1s 3½d. Duty 6d.

In the summer of last year (1884) the population of the United Kingdom was estimated at 35,952,000, *i. e.* close on 36 millions. The total year's consumption was very near 176 million pounds. This gives say 5 lb. per head. The average price of tea all round in bond last year was 11¾d. The duty 6d per lb.*

Two millions sterling is the estimated addition to the revenue which would be realized by the extra 3d on tea duty. The money, alas! is wanted, thanks to the acts of those in power, but any plan is better than squeezing it out of the poor as this will do. Lay the impost on alcoholic drinks. Tax on marriages with a sliding scale optional to all, the lowest a merely nominal sum, the highest a good round one. How very many would only be married on the highest scale, so the tax would be productive! Several taxes might be devised on the same principle, viz., that of making the rich pay for the splendour they have, affect, and cling to. One of the curses of England is drink. The temperance movement is spreading, and it should be hailed with delight and fostered. When a better opportunity than the present? Let those contribute to these wars (Jingo in character) who drink, who make a show, who can afford extra payments, but spare the sober and industrious poor.

Perhaps I am foolish to write in this style, for public opinion in Ceylon can scarcely affect the question, and all interested in tea, myself included, who object to this proposed extra duty, may be considered as mindful of our interests as producers. Well, yes, true to some extent, but in this case our interests jump with humanity and commonsense, and therefore deserve attention.

Figures again. I rather weary of them, and what I am about to mention is against my theory that the proposed extra duty must in a measure affect the producer. The said figures of the last fifteen years show, that, when all-round price of tea in bond was about 1s 5d, any fall in price materially increased the consumption, but, when the said price had dropped to 1s 2d, any further fall did very little that way, so little indeed, that, whatever increase is shown may well be due to the enlarged population, or other causes, and not to the fall in prices. The following sets out what I mean:—

Periods.	Fall in Price in Pence.	Approximate percentage of fall.	Rise in Consumption in approximate percentage.
1869-74	17·8 to 17	4·5	16½
1874-79	17 to 14·7	13·6	10¼
1879-84	14·7 to 11·8	19·8	3½

As regards the yearly consumption per head of the population in the United Kingdom spoken of above, the utmost we have reached yet is 5 lb. But it is curious to see how much larger it is in the colonies. I have not yet got the figures for them later than 1878, but it respectively stood in pounds as follows that year:—United Kingdom 4·66, Victoria 6·92, New South Wales 7·53, Queensland 9·16, New Zealand 11·05. That is to say the denizens of the colonies all drink far more tea than we do here, in New Zealand nearly three times more per head than we did that year! The multiplicity of public-houses in England is the cause; how unwise then to overtax the harmless beverage tea.

* I have taken these figures for thirty years back 1878 and 1884 from a statistical article in *The Times*. But, though in the great leading paper, I have reason to doubt if they are quite correct. Probably, however, they are not very wide of the mark.

In a late article from Ceylon in the *Indian Planters' Gazette* I came across the following:—"A marked change appears to have come over the ideas of tea planters as to the distance at which their trees should be placed in such low altitudes as the valley of which I am writing. Formerly, and at higher ranges, the distance was usually 5×6 and 4½×4½ but now by common consent the distance is made 3½×3 or 3×3½, and it is even a question whether 3×3 might not be adopted with advantage, the object being to cover the ground as quickly as possible. If this is not done, it is felt that years and years of sun and rain pouring down on the soil must have an injurious effect upon it."

My experience is not in accord with the above. China tea may certainly be planted 3×3. Hybrids too, I doubt not, will give more profit the first few years at 3½×3, but I think they would thus be found too close eventually. The object should be to plant not for the present alone but for the future, and 4½×4 cannot be too much for good hybrid plants. What the writer means by "years and years of sun and rain pouring down upon the soil having an injurious effect upon it" I do not perceive. I suppose he means that the soil being left exposed to the sun and rain for years would deteriorate. But I never heard before that sun and rain acted prejudicially on soil. I was surprized to see the above, for otherwise the article is very good and well written.

Whatever the distance decided on, it should, in my opinion, be more one way than the other, so that some clear space be given between the lines. What used to be called "hedge planting," that is, that the trees should touch each other in the lines, and be well apart between the lines, had its advocates in my day. For this plan with hybrids 5×3½ or 5½×3 might do. But, while the plan seemed to me good, I cannot speak from experience of it. Another and a sensible plan proposed (I speak not from experience of it) was to plant hybrids 2½×4, and when the time came they were too close to root out every alternate plant in the 2½ line, thus leaving the eventual distances 5×4. A large yield would thus be got in the early years, and room for the trees to develop later. I always thought well of the idea. I forget whether I or others started it, but that is beside the question.

EDWARD MONEY.

COFFEE AND TEA.—A return has lately been published of the areas under tea and coffee cultivation in India for the year 1883. Regarding the first, an interesting comparison is made between the figures in the year 1875-76 and those in the year under notice. Thus it appears that in the former year in Assam and Cachar 87,307 acres yielded 20,028,890 lb. of tea, and in 1883 189,453 acres yielded 52,171,200 lb. In Bengal 26,378 acres produced 4,941,226 lb., and in 1883 49,753 acres produced 10,703,139 lb. In the North-West Provinces 4,363 acres gave 631,182 lb. as against 7,819 acres giving 1,202,147 lb. In the Punjab 4,246 acres gave 679,949 lb. as against 7,964 acres yielding 1,300,010 lb. In Madras 2,392 acres produced 220,070 lb. as compared with 5,423 acres producing 529,490 lb.—*Madras Mail.*

ECONOMIC ENTOMOLOGY: PLANT-LICE.

Among man's insect enemies, few, if any, exceed in destructiveness the ravages of the Aphides, or plant-lice. Until this very remarkable group of insects was systematically investigated, it was believed that every plant had its peculiar aphis; or, at least, that every separate species of plant-louse was peculiar to some plant. Perhaps the earlier naturalists accepted this theory more readily, because Linnæus, in giving names to many of the family, made the plants upon which he discovered them stand gossip for the insects. This has, however, been found to be by no means accurate; for instance, the oak is found to be tenanted by at least six species, elm by four, firs by eight, and birch by eight; while the terrible pest of the Hop-growers, Aphis humuli, is to be found upon nettles and damson trees as well as upon hops. Some botanical families seem to be exempt from aphis attacks, for we do not hear of any species attached to the Fumariaceæ, the iris, or gentians; and perhaps, with one exception, the same immunity applies to the ferns. Some other plants are exceedingly subject to a "blight" of plant-lice, and it may be generally accepted that all are more subject when poorly grown, either on unsuitable or poor soil, or are in any way in a weakly or degenerate condition.

Perhaps the fact which will first arrest the attention in our study of aphides is the remarkable fecunity of some of the species. It seems almost past the grasp of the human mind to follow the rapid generations and enormous multitude of individuals which may be the offspring in a single season of a single plant-louse. If there were no natural enemies to check the ravages of these, it would soon become easy to calculate when they would have mastered every other animal on the face of the earth, by consuming the plants upon which such could live. As an example of this wonderful fertility, it has been estimated—in fact, very much under-estimated—that a single rose aphis may produce in one year the enormous progeny of 32,768,000,000,000,000,000 individuals.

If a colony of aphides once settle upon a particular kind of plant, it is found that they will almost prefer starvation to a change of vegetable juices; though other colonies of their own species, and founded from the same brood, are comfortably feeding upon the plant to which it is wished to transfer them.—*Field.*

TOBACCO GROWING IN CHILAW, CEYLON.

The *modus operandi* of Tobacco cultivation in the District may be briefly stated as follows:—

For a period of three or four months the land is gradually manured, and then it is thoroughly weeded, ploughed and properly enclosed. The space is next divided by equivalent lines drawn across each other at right angles, and seedlings are planted each on a section and are shaded till they take root. Thus far men alone are employed, but with the watering women commence to take part in the labour. These—all of whom are young—work as hard as any son of Adam. The watering continues for nearly three months, and the labour increases with the growth of the plants, as with it increases the quantity of water required for each plant. It is much to the credit of these female labourers that most of them are able to water regularly (morning and evening) each a plantation of three hundred trees. The worst part of the job is when the crop has to be cured. This requires great skill and experience, and is generally undertaken by men and elderly women, whose power of endurance is admirable. The leaves at first are so placed as to expose their nerves to the sun. After being in this position for some time, they are constantly turned in and out for several days till they change colour, and then they are placed in the shade till they are fit to be sorted out and bundled up for sale. Though this process does not take more than fifteen days to cure a set of leaves, the cultivators are actually at work for nearly two months, as all the leaves in a plantation cannot be cropped at the same time. What the cultivators experience at this stage is nothing short of a roasting in the sun.

How the designing Sambaneara profits by this cultivation is explained by the fact that the class of cultivators under notice during the cultivation (which takes up five months) are supplied from time to time by these boutique-keepers with rice and sundries at exorbitant rates upon Pro-notes carrying usurious interest—which they call "Profit"—from the date of execution. By this means, when the crop is cured and sold, a great portion of the money realized thereby goes into the coffers of the *Shent per Shent* Sambancara; and what remains to the cultivators is mere nothing in the way of adequate compensation for the sweat of their brow.

If some liberal person will advance small sums on easy terms to these indigent cultivators, the Sambancara will not be resorted to, and a saving,— by no means small, will be effected to the cultivators.—"Examiner."

INDIA *VERSUS* CHINA TEA.

We read in the *Leeds Mercury* the following letter from Messrs. Brooke, Bond, and Co:—

To the Editors of the Leeds Mercury.

GENTLEMEN,—At the present moment, when the renewed activityof the French fleet in the China seas is causing considerable disquietude to the mercantile world, we think it desirable, through the medium of your valuable journal, to call attention to the fact that the British public are far more closely interested in this Franco-Chinese conflict than they appear to be aware of. The staple trade of this country with China is in tea; and statistics for 1884 disclose the fact that the proportion of China teas imported stands at 66, as compared with 34 in India tea. We leave to the imagination of the reader the result in the price of tea, in the event of a real war and a strict blockade of the Treaty ports by France. Moreover, John Chinaman, when in difficulties, has an awkward system of raising the wind out of the foreigner, by an extra war tax on all exports. Permit us to point out a remedy for this uncertain state of affairs in the capabilities of England's great Eastern Empire.

Tea cultivation in India, as compared with the same industry in China, is a thing of yesterday. It was only in 1834 that Lord William Bentinck, who was, perhaps, the most enlightened Viceroy ever possessed by India, appointed a Committee to investigate the subject; yet the dimensions it has even now attained are extraordinary. The term "Indian tea" includes the products of widely separated districts, presenting great diversities of physical character, but the reasons of its steady success are easily stated. It is grown from a plant superior to the Chinese, and in a richer soil; it enjoys a hotter and more forcing climate, better modes of cultivation, and improved machinery for preparing the leaf. We have no hesitation in stating that in Hindostan England has a field wild enough to supply all Europe with tea. What is chiefly needed to help our Indian planters is a steady demand, so that more jungle may be cleared, to show a profit. Let tea-drinkers ask for and buy only Indian tea. They have everything to gain by doing this. They are helping a new British industry, and opening new outlets for English capital to be safely and profitably invested; they get better value for their money, as Indian teas are richer, stronger, better in flavour, more economical; and lastly, they are never adulterated. This last is more than can be said of many varieties imported form China.

The importance of this subject to British commerce is our apology for trespassing on your valuable space. Faithfully yours, BROOKE, BOND, & CO.—*Indian Mercury.*

AN INDIAN TEA PLANTER ON CEYLON TEA ESTATES.

SIR,—Having lately accompanied an Indian planter of long and varied experience through a few of our tea estates, both at high and low altitudes, I think you might like to hear the impressions conveyed to my friend during his trip. I put on one side as an oft told tale his surprize and wonderment at the extraordinary growth of our tea, or the abundant and never-ceasing flushes—those things are the first thing an Indian tea

planter notices. My friend had never been in Ceylon before, and was, he tells me, agreeably surprized with much of the soil he saw after what he had heard of its comparative poverty.

Of course, much of the land now being planted with tea would hardly be opened if in India; but, in view of the very much higher cultivation evidently undertaken here, he says he should have little fear of the ultimate result. One thing struck him very forcibly, and I think it an important point: he was of opinion that so far we had obtained a very excellent jât of tea, evidently well-suited to the country. I was told of many estates in India, one of which had been under my friend's supervision, which, though excellent in soil and situation, refused to give paying flushes owing to the low-class of hybrid planted on it. The Calcutta agents reluctantly gave their sanction to a gradual re-planting of the whole on this account. He was struck with the uniformity of our jât, considering the wide range open to us to choose from.

According to my friend, tea planting in India is in a terrible bad way. Proprietors of most gardens are at their wits' ends for money to carry on, and agents in Calcutta were foreclosing right and left. If half I was told was true, more profits have been made by the Calcutta men than ever have accrued to the planter. This is a state of things there which cannot last, however. There appears to be any amount more land fit to be planted with tea in India, but farther and farther away from roads; and to open much of such land in face of present low prices and cost of transport in India is looked upon as madness by many.

One remark made by my Assam friend is in reference to the cleanliness of our estates as compared with the comparative jungle with which most gardens in India clothe themselves at various seasons of the year. He said he thought in this at least we were wrong, for inasmuch as however closely we planted, the soil must be exposed to the burning sun for a very considerable portion of the year, which could not be a good thing. If we allowed a certain amount of undergrowth to spring up, particularly before pruning, it would shield the ground from this awful scorching. As I remember seeing something in your paper on this subject on the occasion of your last visit to the Kelani Valley, I thought I would let you have a line.—W. H.—Local "Times."

CINCHONA CULTIVATION AND THE AUCKLAND DOMAIN.

The following is the copy of a letter sent to the City Council upon the above subject by Mr. W. Goldie, Domain Ranger;—"To P. A. Philips, Esq., Town Clerk, for the information of His Worship the Mayor and City Council. Sir,—Some correspondence having recently appeared in the public Press regarding the cultivation of cinchona, in which reference has been made to these plants under my care, I have thought it necessary to bring the matter before you, and have the honour to report as follows:—During the spring of 1883 and autumn of 1884 there were 2,000 plants raised and dealt with in the following manner: The first lot, consisting of 50 of the best plants, was taken from the pots in the middle of December, 1883, and planted out in a specially prepared bed, shaded and watered until thoroughly established. In the end of January, 1884, all shading and watering was discontinued. The plants, when first placed outside, were 2½ inches in height, and by the beginning of May, 1884, they had attained a height of about 8 inches, and were fine vigorous plants. About the end of May, 1884, severe frost made its appearance, and destroyed every plant. The second lot, which consisted of about 1,600 plants, was potted off during the spring of 1883, and plunged in sand in the greenhouse, where they were allowed to remain all the season, by which time they had attained a height of from four to five inches. Early in April, 1884, they were removed from the greenhouse and placed in the open, so that they might get thoroughly hardened and fit for distribution amongst our settlers. From the time they were placed out until the end of May, 1884, they kept in good condition, but immediately after that date, they were badly injured with the frost. Some of those were distributed, and the balance which was retained on hand all died. The third lot of plants, the balance of the 2,000, which numbered about 300, was potted off during the spring of 1883, and kept in the greenhouse till about the first of August, 1884; then taken out to be hardened off. About the end of August they were planted out in the ordinary nursery rows. Of the number so dealt with there are now only 45 plants alive, the largest of which has attained a height of about seven inches. Those plants are now about eighteen months old, and I am reliably informed that plants of this age, grown in Ceylon, would have reached a height of about two feet. The varieties dealt with above were principally *C. succirubra*, *C. ledgeriana*, and *C. officinalis*. Last winter, a short time before the Domain was taken over by your Council, the late Domain Board purchased some seed of *C. hybrid*, and instructed me to grow it. At the present time there are from 5,000 to 6,000 plants in stock, and they will be further experimented with this autumn as you may direct. In giving the above details, I cannot forbear from making a few remarks regarding a letter from Mr. W. L. Malcolmson, which appeared in the *Herald* of the 15th December, in which he states that the cinchona plants in the Domain were planted out at what he considered too early a stage. Some time early in the spring of 1883, Mr. Malcolmson paid a visit to the Domain after the seed was raised, and a number picked out. He was then told by me of the course I intended to take in experimenting with the cinchona plants, and with my suggestions he entirely agreed. Not only so, but a few weeks later, in answering a letter from Mr. Duncan, of Wellington, he distinctly forecast the experiment tried by lot second. His letter of the 15th inst. was the first intimation I had that he dissented from the course pursued." —*Auckland Weekly News.*

UNFRUITFUL TREES.

How often one sees and hears of trees that are unfruitful, and Apples and Pears especially so. Now this should not and need not be if proper means were employed to remedy it. Nothing is more disappointing than year after year to expect fruit and get none, or of such poor quality as hardly to be fit for use. Some trees are no doubt too old, and would be better replaced by young ones, but others, both standard and trained, can be brought into a fruitful state, and the treatment will often entirely cure canker, which no doubt is caused by poverty in a great many instances. Very generally this unfruitfulness is caused by the roots getting down into the subsoil for moisture in dry seasons, and when there, as they do not find any of the elements that are necessary for building healthy growths, the tree gets into an unhealthy or an unfruitful state, often making wood at the expense of the fruit-buds. This must not be taken to be always the case because some trees seem to run all to fruit-buds and yet do not ripen their fruit.

Young trees can be lifted and brought into a fruitful state by bringing the roots nearer the surface, but trees that have stood in one position, for twenty years or more, cannot be lifted entirely, or if they were lifted they would hardly recover from such severe treatment. What is necessary to do in such cases is this. Cut away the roots that have a tendency downwards. The way to proceed with this operation (and I have practised it myself on a great number of trees and found it bring about the desired result) is to open a trench on both sides of the tree (if a standard), 6 feet from the stem, 3 feet wide and about 6 feet long, parallel to each other, removing the soil from the trenches to the depth of 3 feet, taking care not to injure the roots that lie horizontally; then work towards the stem with steel forks and remove the soil as the work proceeds until within 18 inches of the stem, tunnel the remainder, and sever the tap or perpendicular roots about 2 feet from the surface, cutting the upper portion of the roots smoothly with a knife and removing as much of the remaining part as possible: then proceed to fill in the trench, making it firm beneath the ball of earth. If some manure can be worked into the upper 18 inches

of soil it will encourage fresh roots and greatly assist in stimulating the energies of the tree. This pruning will check rank growth and consequently direct the energies of the tree to the formation of fruit-buds.

Trees on walls must be done from one side only, removing all downward-stretching roots quite back to the wall. Trees that produce nothing but bloom are easier dealt with: Pear trees especially are liable to get into that state; they make no wood, nor in my opinion do they perfect their fruit-buds. The best way to operate upon them is to thin out the head of the tree about a third of its branches if a standard, and to give it a dressing of rich manure. Trees treated in this way, and which have not had any fruit for years previously, fruited well the next year. A great deal of good can be done to trained trees by the removal of spurs, thereby causing fresh ones to push. In the case of some sorts it is necessary to cut them all back to the main shoot, and the trees of some kinds refuse to bear fruit on old spurs or limbs; pertinaciously obstinate is Gansel's Bergamot Pear, and some others that fruit best on a system of moderate extension. This is work that can be carried on at almost any time from the beginning of September until the end of February, frosty weather expected.—A WATERMAN, Preston Hall Gardens.—*Gardeners' Chronicle.*

QUEENSLAND: ITS SUGAR AND AGRICULTURAL INTERESTS.

The following extracts are taken from a recent letter of a practical and experienced colonist, who has spent upwards of twenty-two years in Queensland:—

Mackay, Dec. 28, 1884.

I am glad to learn from your last letter that you think the sugar planters will come out of the present struggle with low prices better than the beet growers; but my opinion is that the cane growers are losing quite as heavily as the beet growers, notwithstanding the higher percentage of sugar in the canes. It is more the cost of production than the existence of a higher percentage of sugar in the raw material. At any rate land is being thrown out of cultivation here, and in a couple of years the industry in this country will be dead, or very near it.

In Queensland we have, unfortunately, a government that is hostile to capital, no matter in which way it may be attempted to be used; thus, in the case of sugar, where black labour is specially useful and economical, the Government have exercised their hostility to the industry, by pasing vexatious regulations, which have practically cut off our available labour supply.

The result of the last election has been that ten millions are to be borrowed and spent in making what have been dubbed political railways in various directions, and the interest on this large sum is to be obtained by means of a new land bill, whereby the squatters are to be made to contribute this money.

Thus it is intended to resume one-half of the runs, and cut them up into 20,000 acre blocks, with a rental four times as great as the squatters have hitherto been paying. By this plan it is hoped that young men from the old country may be induced to come out and invest their little capital. God help them if they do. I enclose a speech of Mr. Stevenson in the House during the debate on this land bill, which will give you an idea what chance these young men will have.

Under the provision of this new bill certain districts will be set apart for agriculture, in which a man may take up 960 acres at 3d. per acre, and he must live on it for ten years before he can purchase some, and then only by paying £1 per acre. The thing is so ridiculous, because, subject as this country is to periods and seasons of long drought, it is quite possible that at the end of ten years, or half that time, the poor farmer would not have as many shillings as acres in his hands.

The amount of capital required to take up a grazing area of 20,000 acres, and carry out the conditions of the Act, is £7,000, and no one can see how any interest can be paid on it; of course, the rent is something to go by, but the probable sales must guide the investor.

Fancy 3d. per acre as rent per annum for agricultural and! surely it must be worth more or not worth taking up at all? It would be useless to attempt to give all the absurdities of the bill, but I may mention that the holders of land are to be blocked in every way from making the most of their property, or in disposing of it as they may desire after their death. If A. dies and leaves his farm to B., who owns a farm already, then B. must sell one of his farms within a given time, otherwise he must forfeit one. Again, in selling one of these farms, he must sell to some one who does not already own a farm, so that his chances of selling well are reduced very considerably.

Never was a Christmas time spent in this district when the prospects of the future were so much clouded. In the town everybody in business is looking and feeling queer. It is supposed that our population is not much more than half what it was last year; this means, of course, ruin to business men. Crushing is over, and the sugar returns not much more than half what they used to be; this is the result of the drought last year when the canes were young. The young plants for next crushing have had a better chance and give promise of a better crop, but the cry all round is, how are we to get the canes off the land now that we have no labour? We must hope for the best, and in the meantime I am throwing all my other land out of cultivation. At any rate, I should be sorry to see young men coming out here with their little fortunes and investing the same in what we know, from experience, must lead to their ruin. Young Englishmen are so apt to think the advantages here are greater than they really are. They compare them with existing conditions in England, but there really is no comparison whatever between them.—*Field.*

OUR SUGAR LANDS: THE CLARENCE RIVER DISTRICT, NEW SOUTH WALES.

From the Clarence Heads to Grafton is one long panorama of picturesque scenery. The broad stream with its numerous fleet of crafts would alone furnish interest to the visitor as he passed up between its banks bright with cane, dotted with quaint looking mills, and chequered every few miles by clusters of white houses and tiny wharfs, where miniature shipping depôts have been formed. Here and there one sees a plantation of bananas, then a long fringe of cane, and passing round a projecting point, a township on the back comes in view. And so on for miles. Then the little steamer, with its load of well-to-do looking farmers, their buxom wives, and pretty daughters, puffs busily past one of the beautiful islands that stud the river—Chatsworth, Woodford, Brushgrove, and many others—each one, as the impression of the last fades from the mind, apparently more picturesque than its fellow. The steamer's course is most erratic—now it steers to this shore, now the other; picking up passengers at little jetties along the route. Then a drogher, with a great punt laden with cane on either side, comes slowly down stream, the little vessel almost lost to sight between its big unwieldy companions. A minute afterwards we pass an ocean-going steamer, trim and neat, its passengers waving their handkerchiefs to the launches as they pass. It is bound from Grafton to Sydney. At each township where our boat touches there are passengers coming and going, and all with the same prosperous appearance in their attire and there are chubby children everywhere, some playing at mud-pies near the wharfs, others gathered to see the boat come in, others with books strapped together bound for school. I cannot help thinking I have reached "the happy land" at last. "And is this all the effect of sugar?" I ask a companion. He smiles, and gravely shakes his head. "Then, if not, what is the cause of all this bright cheerful air of comfort and content?" He utters but one word. It is "corn." And then he tells me that as a whole the farmers—the growers of produce, not the manufacturers of sugar—are in an excellent position, the good price for corn during pretty well the past three years having lined their pockets well. "Far more of this prosperity you see is due to corn than sugar," so he said. And then I remembered that, standing by the river side, I had asked an old resident, a grizzled fellow, with many grey hairs and few sound teeth, who had lamented over the failing fortunes of sugar-making, what it was that kept the district going, and be answered with the air of an oracle, "It's the corn as does it."

The following interview with a millowner on the Clarence River gives a very fair idea of the general opinion expressed to me with regard to the prospect of the sugar industry on the Clarence:—

"The sugar industry in this district has," he said, "I think reached a climax. In fact, I think, it is pretty well 'played out.' It is going to be a struggle between white labour and coloured, or some similar labour which will be cheap and reliable. In countries where black labour is used sugar can be grown and manufactured for less than we can do so here, even with the handicap of the £5 duty. We have to pay what is really—when its unsatisfactory character is considered—an extraordinary price for white labour, and even with the duty we are not able to compete against the outside sugar countries. Sugar for which we got £32 per ton last season is now selling at £24. One of the members of an important sugar company in Sydney informed a proprietor of this mill when on a visit to the city that they could import sugar into the colony and pay the duty, and yet that it would stand them less in cost than sugar of a similar quality manufactured on the Clarence. Of course if that can be done it is 'all up' with the sugar industry in this colony.

"Some five or six years ago our average crops of two-year-old cane ran from 50 to 60 tons to the acre, but this season cane of a similar growth will only yield on an average up to 35 tons to the acre. Even allowing for frost and drought, on our richest land we cannot get more than 45 tons of two-year-old cane. Many growers are now going in for annual cane. It takes the full 12 months, in fact more, to bring it to maturity. I cannot see how sugar-making can pay the owners of small mills, but it still pays the growers fairly well. The yield will have to come down to 26 or 28 tons to the acre, and then it will be ploughed out, and we will all go back to corn again. When I first started in this district all the land surrounding the mill was under sugar, but now you would have to walk for 10 minutes before reaching the first patch of cane, and it is only 5 acres in extent. We have now to send a punt and steam launch up and down the river to get enough cane for the mill.

"The real cause of the present prosperity of the district is corn, not cane. Corn pays well here, and has done so far nearly three years past. Some years ago corn fell in price, and it was ploughed out and cane put in. Then corn went up and cane came down, and in went the plough among the cane, and corn was started; and so it was, up and down, for a considerable time until the frost attacked the cane severely, and then many abandoned it finally. The following return of yields from cane-patches, the produce from which has been crushed by us during the present and two past years, will give an idea of the yield of cane in this district:—

In 1882.		In 1883.		In 1884.

THE CULTIVATION OF WATTLES.

The following is a digest of a report on the cultivation of wattles by Mr. J. E. Brown, the Conservator of Forests, which was laid on the table of the Legislative Council in Adelaide, South Australia. Mr. Brown says:—

It is an undoubted fact that the bark of our wattles is most highly appreciated by tanners in Europe and elsewhere, and that were the supply regular, good in quality, and up to the demand in quantity, the result would be a regular market for all we could produce. No bark or other material has yet been found in quantity which contains an equal percentage of tannic acid to that of the broad-leaf wattle. Our colony is the principal habit of the tree, and hence it remains with ourselves to command the market by the production of a thoroughly reliable article. There is no doubt that of late years, owing to the comparatively inferior article gathered, as well as the gradual decrease in quantity available, our name as producers of wattle bark has been seriously affected in the European market. It is only within the last few years the fact has dawned upon the public mind that the wattle-tree is capable, by systematic application, of being cultivated as a highly remunerative crop. That it is so there can be no doubt, and it is evident that the proper cultivation of the tree opens out for a large section of our farmers an industry which will yield a return far more handsome than they have hitherto been receiving from cereals or stock.

GENERAL DESCRIPTION, PHYSICAL PREDILECTIONS, AND RELATIVE TANNIC VALUES OF THE WATTLE-TREES NAMED.

For the guidance of those who may wish to enter into the cultivation of the wattles as a crop, it is essential that the fullest information should be at once given in regard to the general peculiarities of each of the species referred to, their relative tannic values and adaptibility to the soil and climate of the various districts of this colony. These matters I shall now endeavour to give under the respective names of the trees. Acacia pycnantha, or the Broad-leaf Wattle.—This tree is common to nearly all districts of the colony north of Encounter Bay, and is occassionally to be met with along the coast from Kingston to the Glenelg River. Its principal habitat, however, is in the Adelaide hills and plains, from Encounter Bay to Clare. For propagation purposes, seed should, if possible, be obtained from trees grown within these limits. In some parts of the North there is a narrow-leafed variety, with the stem and branches covered with a whitish substance, which it is desirable should not be propagated, as the tree is of slow growth and not attain payable dimensions. The species will grow readily in almost all kinds of soils, but its rate of growth is most rapid in those of a sandy character, while at the same time the largest trees and the best bark is produced on sites where the soil is sandy on top and of a good retentive clay in the subsoil. With this tree we have the means of making our poorest soils yield valuable crops, instead of them lying comparatively idle and worthless. In the South-East there are few at all presentable places where this tree will not thrive. A. pycnantha will do equally as well, and on the richer soils. In the northern portions of the colony, that is north of Encounter Bay, to the present limits of agricultural settlement, more care will have to be exercised in the selection of sites for wattle plantations than is necessary in the South-East. Taking the block of country lying between Encounter Bay in the south, Mount Remarkable in the north, Spencer's Gulf on the west, and on the east from the River Murray, along the line of the present limits of cultivation, the hilly portions of it are all the natural habitat of the species. Where the soil is suitable on the plains and other portions within these four lines, not embraced in the previous class of country, the broad-leaved wattle can be cultivated with every probability of a payable crop. Within the district defined there are many places where it would not pay to cultivate the tree. Although it will grow to a fair size on highly calcareous and saline soils, and yield an average percentage of tannic acid, still where these kinds of soils can be avoided it is as well to do so. On such soils the growth is unusually slow, and the trees die off at an early age. It is advisable also to avoid sites where the soil is very stron

clay on surface, unless thorough cultivation in the way of stirring up soil by ploughing or scarifying can be afforded every year. Of all the acacias to which this report has reference, the bark of the one under review contains the largest percentage of tannic acid. According to experiments instituted by Baron Sir Ferd. von Mueller, the Government Botanist of Victoria, it yielded, when artificially dried, from 30 to 45 per cent of tanning matter. During the last year some interesting analyses have been made by Mr. George Goyder, jun., of the Survey Department laboratory. As the result of the analyses [given in detail in the report], Mr. Goyder makes the following remarks:—"The thickness of the bark appears to have little or no effect on the proportion of tannin. The age of a tree at which the percentage of tannin in the bark begins to fall off varies according to the soil, climate, &c. As long as a tree looks healthy and strong, and has a general appearance of sturdy growth, the percentage of tannin in the bark does not appear to diminish with age. Thus, although the tree at the Semaphore was about thirty years old, the percentage of tannin it yielded was only slightly below the average, the average for the twenty samples of trunk bark examined being 26·17 per cent, the lowest 17·4, and the highest 31·0 per cent of tannin. In unhealthy trees, on the contrary, even though young, the percentage of tannin falls off at once, as is shown by those of Hundred of Bright and the Bay-road. In both of these cases the trees were described as unhealthy and apparently dying. Some of the trees on Torrens Island were also unhealthy, and showed the same results. The tannin in the bark in two-year-old twigs is on an average 4 per cent lower than that of the trunk bark from the same trees. The bark from the one-year-old twigs, in the only case tried, contained 3 per cent less tannin than the trunk bark. The leaves contained on an average 4·3 per cent of tannin, but as their total extractive matter averaged between seven and eight times this amount, they could probably only be employed as a weak solution for tanning, and even then the presence of the large amount of gum and other extractive matter might be prejudical to their use." A special feature of Mr. Goyder's ananysis is that the bark upon the branches and twigs of this wattle contains a very high percentage of tannic acid. This fact points to the necessity of stripping all available bark from the trees. During the summer months this wattle exudes a very considerable quantity of gum, which is used for the same purposes as the well-known gum-arabic. With the conservation and cultivation of the trees such as is now advocated, an opportunity will again arise for the revival of this industry amongst us. Acacia decurrens, or Black Wattle.—This tree is indigneous chiefly to Victoria and New South Wales, and it only appears in the South-Eastern district of this colony where it is of frequent occurrence, and attains to a comparatively large size. This species of our wattle delights in sandy soils with a clay subsoil; but it attains its largest dimensions upon a black alluvial soil of great depth, and where there is plenty of percolating moisture. It will thrive well and make very considerable progress in very poor situations where the soil is almost pure sand. It does remarkably well about Adelaide, as instance some fine specimens in the Botanic Gardens and Park. From my experience of the tree I am of opinion that while it will do well in almost any kind of soil, it will not grow satisfactorily and as a payable crop on exposed situations, or where the rainfall is below 15 inches annually. I can therefore only recommend its cultivation in the moisture and more temperate portions of the colony. It is recommended by Baron Mueller for planting upon worn-out lands overgrown with sorrel. Its cultivation upon our South farms in the neighbourhood of Strathalbyn, and in the older-settled districts among the hills, would therefore be advisable. The climate and soil of these districts are suited to its cultivation. According to analysis made under the direction of the Victorian Wattle Board, the bark of A. decurrens yields from 29 to 34 per cent of tannic acid. Upon the bark of a tree twelve years of age, grown near Mount Gambier, Mr. George Goyder's observations are as follows:—"Thickness of bark, 0·34 in.; per cent of tannin, 27·5; and per cent of extractive matter, 14·7. This species can be cultivated as readily as A. pycnantha. After bushfires run over any district composing its habitat, it springs up in abundance. The tree is somewhat branchy in its habit, and requires close planting in order to check this and make it throw its woodmaking vitality into the stem. One pound of seed is said to contain as many as 40,000 grains. These can be germinated with less heat and earlier than those of the broad-leaf species." Acacia saligna, or the Western Australian Wattle.—This tree is now under experiment at the Wirrabara Forest Nursery, but nothing can yet be said as to its adaptability or otherwise to our conditions of soil and climate. Acacia dealbata, or Silver Wattle.—In this colony the silver wattle is confined to the South-Eastern district, but unfortunately its bark is comparatively thin and weak in tannic acid.

THE SYSTEMATIC MANAGEMENT OF INDIGNEOUS AND PLANTED WATTLE ENCLOSURES.

Under this heading I shall make some general remarks in regard to the best methods to pursue in the treatment of natural-grown wattles, and of putting land under a crop of the tree by artificial means, so that the profits may be realized which I maintain can be procured from their cultivation. Unless where the name of a species is specially referred to, the term "wattles" will apply to both A. pycnantha and A. decurrens in a general way. First in importance to the wattle farmer is the subject of how best to treat the seed so that it may germinate in a reasonable time after being put in the ground. The outer covering of the wattle seed is of great hardness, and requires the adoption of extreme measures before it will burst and permit the embryo to expand and start the young plant. With this seed nature's method of germination appears to be a very slow one, as it is known that it will remain in the ground for many years before sprouting takes place. The application of one winter's rains to it does not have the usual effect produced on most kinds of seeds, and it appears to require several years of saturation before the hard covering becomes soft enough to permit germination. One of the most effectual natural means of hastening their germination are bush fires; after one such, over ground upon which the wattles have grown naturally, thousands of young plants spring up. This fact is well known to all colonists. There are two methods of treatment adopted in the preparation of the seed before sowing. Both of these are effectual and have their respective advantages. The first is to subject it to the softening influence of hot or boiling water. Hitherto, in referring to this process, I have recommended that the seed be placed in a vessel and almost boiling water only poured upon it and left to soak for one or two days; after this the seed to be taken out and kept damp in a bag until signs of swelling takes place. From experiments lately made however, by Professor Tate, of the Adelaide University, of treating the seed to various degrees of hot water the fact has been conclusively demonstrated that it will stand partial boiling without injuring its vitality. As these experiments are of vital importance to the wattle industry they have been handed to me for publication. They are therefore given in full as follows:—Experiment 1. Acacia pycnantha—Equal parcels of seeds saturated with water at the following degrees of temparature—150°, 170°, 190°, 200°, and 212°. The seeds germinated in about equal proportions at end of three weeks. Experiment 2. Acacia decurrens—Seed saturated with boiling water, and kept in wet sand in a warm place; germinated at end of two weeks. Experiment 3. Acacia saligna—Seed saturated with water at 212° of heat, July 22; seeds began to burst July 29. Experiment 4. Acacia pycnantha—July 22—Boiled for one minute, three minutes, five minutes, and seven minutes respectively. All the seeds germinated August 9. The second method of treating the seeds is that of subjecting it to a slow fire to such an extent that the outer covering only is slightly cracked without injury to the embryo. The advantage claimed for this method of preparation is that the seed can be sown either broadcast upon the ground without covering or dibbled in the soil in the ordinary way at any season of the year, and especially before the winter's rains set in, and then lie dormant until such time as sufficient moisture falls to germinate and nourish the young plant successfully through

its early stages of life. Against the system there is this to be said, that unless care be taken, a considerable waste of seed takes place by overburning. Of the two methods, the one first described is perhaps most likely to be successful with intending growers who have not had practical experience in dealing with the seeds. I shall give some suggestions with regard to the treatment of natural wattle ground. In districts comprising the natural resort of the tree there are many spots which are too poor for either grazing or agricultural purposes, but on which it grows naturally if the ground be protected from stock and fires. It may be that these are covered with a sparse crop of gums, or not being so are yet of too rough a character to admit of cultivation by the plough. To put such character of sites under wattle I have to advise—first, that they be thoroughly enclosed against stock of any kind. All undergrowth should be grubbed and useless trees cut down during the summer, and the whole spread out so as to cover the surface of the enclosure as much as possible. It is of course understood that the site was previously occupied by wattles, and that the soil contains seed to a more or less extent. In case, however, the latter should only be in patches here and there, it is advisable to broadcast fresh seed all over the ground, so that the crop may come up regular over it. The above operations all completed, then about the end of summer, or just before the winter rains set in, the whole should be thoroughly fired and then left for the crop to come up. On light soils, especially the above process, if properly carried out, is almost certain to result in a good show of seedlings during the first season. It may be found, however, that there are places upon which the seed has not germinated, and on these other seeds should be put in with the spade, at the end of the first year if possible. When the young plants are about one foot in height, the ground should be gone over by thinning and pruning, so that when completed the best trees will be left standing with one stem only, at distances ranging from four feet to six feet apart. With a little attention in the way of pruning during the second and perhaps third years the crop may now be left to mature itself. Now, a word to those who may have wattle ground upon which there is a young crop growing naturally, and in various stages of growth. Thinning and pruning should be carried out on them at once. Where the trees have grown up very thickly together—like whipsticks—as I have seen in some parts of the Adelaide hills, thinning only is necessary; but even this should be done with much care, and only partially at first, as the effect of too much light being let in upon those left will retard their growth, and probably cause disease. Where the trees are about the proper distances apart, but still are somewhat branchy, and perhaps contain two or three stems, they should be well pruned, and, of several leaders one, only, and the best, left. In open spaces where the trees are decidedly too far apart, and of course very branchy, they should be trimmed up and endeavours made to encourage a thicker growth by either dibbling in seed or stirring up the ground with a scarifier, so that the seed from surrounding trees may find a bed and have a chance of germination. Of course, the trees of all ages should be properly pruned and care taken to prevent crowding at any stage. In natural-grown forests of wattles, such as I have been referring to, it is expected that there is a regular succession of young trees of all ages, on nearly all portions of the ground. Every year will produce its number of trees, more or less according to the favourableness or otherwise of the season for germinating the seed. In this way there should always be a certain number of trees available for stripping each year, which must be removed in order to make room for the gradual development of the next succeeding rotation, and so on. Hence, as the various ages of growth are mixed together, it is necessary that the operations of stripping, thinning, and pruning be gone through annually, in order that the health and development of the forest may be maintained throughout. We next come to consider the process by which lands upon which wattles never grew can most profitably be put under a crop of the tree. In order to meet all cases of this kind it will be necessary for me to refer to it under the two heads—land upon which the plough can be used, and that which is of too rough a character to admit of this being used. With regard to the first-named class of country I advise as follows:—That the ground first of all be thoroughly ploughed to a depth of not less than four inches. Following this operation one or two seeds should be put in at about from three to four feet apart, in straight rows 5 ft. apart, all over the plantation. The means adopted to distribute the seed in the manner described may be either by hand or machinery. To those about to engage in the wattle industry upon a large scale I would certainly recommend the use of machinery upon open land. During the first two year's growth of the plantation the vacant spaces between the rows should be thoroughly opened up to the action of the air, light, and rainfall by a scarifier. At the end of the first year the rows should be gone over with the view of thinning out each spot sown to one plant only, and this of course to the most promising. When the young plants left from the thinning operation have begun to grow freely, they should be regularly attended to for one or two years in the way of pruning. Afterwards the trees may be safely left until they come in for stripping. I shall now refer briefly to the class of country where the plough cannot be used in the preparation of the ground for the seed. In this case the crop will have to be put in with the spade. During the early years of the plantation's growth the operations of thinning and pruning should be carried out with regard to an enclosure of this kind the same as is recommended for land where the plough can be used for putting in the crop. With regard to the distance apart at which wattle can be grown to the best advantage in every respect, I am of opinion that until the age of six or eight years they can be successfully developed at distances ranging between four feet and six feet from one another, but that after that period they should stand between eight feet and ten feet apart. The best period for pruning is during the months from January to March. Sowing the seed should be done immediately after the winter season has thoroughly set in.

PROFITS TO BE DERIVED FROM WATTLE CULTIVATION.

We now come to consider the most important subject of this report, namely, that of the profits which may be derived from the cultivation of the wattle-tree. At the distances apart which I recommend the trees to be grown—namely, four feet to six feet—there will be an average of 1,200 trees to the acre. In order, however, to make due allowance for blanks, I shall base my calculations upon there being 1,000 only to each acre. At the present time bark is selling at £7 10s. and £8 per ton, and there is every chance of a still higher price being obtained for it during the next few years. Still, to be on the safe side, I will put its value down at £5 per ton only. I give five tons as the probable yield per acre. That this is a low estimate will be admitted, when it is considered that this only allows for 10 lb. of bark to be taken from each tree. I shall now give a tabulated statement of the probable revenue and expenditure during a period of seven years, in connection with a wattle plantation, formed upon 100 acres of land specially purchased for the purpose, and upon which wattle had not previously grown. *Revenue.*—To value of property increased and improvements, say £400; value of 500 tons of bark at £5 per ton, £2,500; total, £2,900. *Expenditure.*—By purchase of 100 acres, at £3 per acre, £300; cost of substantial fence all round, say, 1½ miles, at £50 per mile, £75; ploughing 100 acres, at 8s. per acre, £40; cost of 30 lb. of seed, at 1s. per lb., £1 10s.; labour sowing the seed in rows, say at 5s. per acre, £25; scarifying between the rows twice, at 4s. per acre, £20; thinning and pruning for two years, at 10s. per acre per annum, £100; forming firebreaks during the third to seventh year, say £5 per annum, £25; sundries, £50; interest on money expended during the seven years, say £280; cost of stripping 500 tons of bark at 2s. per ton, £250; balance, being clear profit, £1,108; total, £2,900, thus giving a return of 7 per cent upon the purchase of, and improvements upon, the property, as well as a clear profit of £1,108 over and above that amount.

OTHER KINDS OF TAN-YIELDING TREES RECOMMENDED FOR CULTURE.

It is admitted that in the bark of our wattles we have perhaps the best material in the world for the heavy or ordinary sorts of leather. For the production of the fine sorts, of goods, however, our tanners require the tan-yielding products of other plants, which at present they have to import for this purpose. In order, therefore, to encourage and extend our leather industry, I have to recommend that the following-named plants, which produce some of the finer sorts of tannin matter, be cultivated in the colony:—Quercus aegilops, or Valiona Oak.—The cups of the acorn of this tree are largely used by the tanner. They produce a rich bloom to leather. It may be cultivated in the more temperate portions of the colony. Rhus coriaria, or Sumach.—A small tree, which would grow well in the Adelaide hills. The foliage and branchlets yield a rich tannin, which is much used in the production of turkey and other valuable leathers. Salix alba, or White Willow.—Produce an excellent tanner's bark for such goods as glove leather. The trees grow readily in the cooler districts of the colony.

The above, with others, are recommended by the Victoria Wattle Board for culture in that colony.—*Adelaide Observer.*

CULTIVATING WATTLES FOR BARK IN AUSTRALIA.

Since the natural supply of wattle bark in the Australian colonies has become limited, bringing about a corresponding rise in price, the question of cultivating the tree especially for the highly valuable tanning material has been frequently discussed. That there are many portions of all the colonies where the industry would probably be successful has been generally admitted, and the more the subject is investigated the more clearly does it become evident that the cultivation of the wattle tree offers a wide field for profitable investment. The rapid growth of the tree, the fact that it flourishes upon poor soil of little value for any other purpose, and the certainty of a high price for the bark, all favour the presumption that wattle cultivation would well repay attention. It is, of course, important that a supply of bark should be kept up in order that the tanning industry may be maintained and extended, but the vital question in connexion with the subject is whether or not the bark will pay for production. A great deal could be done in the way of augmenting the supply by closing up state forests where the tree grows, and preventing the stripping of bark until trees attain certain dimensions, while the formation of plantations upon state reserves would also be certainly remunerative and beneficial to the community. But it is further probable that in many localities private individuals might profitably devote their land to the cultivation of the best bark-producing varieties of wattles. Much information and many valuable suggestions upon this subject are contained in an official report obtained by the Government of South Australia. Mr. J. E. Brown, F. L. S., Conservator of Forests for South Australia, has prepared a return in response to an order from the Legislative Council, and the report deals at length with the various aspects of the subject. It appears from the report that the subject is much in the same condition in South Australia as in Victoria. Stripping bark from the natural forests of wattle trees was for a long time a profitable industry. There was much stripping but no planting, and as the trees became scarce the bark was taken from the small saplings; so that the forests were unable to replace the trees destroyed. The result has been that the bark industry, as well as the various trades connected with it, has been seriously injured through the want of forethought and proper management. The quality of the bark is referred to as being superior for tanning purposes to that of any other material, and its appreciation by the tanners of Europe and elsewhere is believed to guarantee a good market for all that could be produced. In regard to the different varieties, Mr. Brown gives particulars as to the quality of the bark and the habits of the trees as well as to the conditions of soil and climate most favourable to their growth. The Acacia pycnantha, the broad leaf or golden wattle, is described as one of the best varieties, yielding the best quality of bark, being hardy and quick-growing. It is said to grow well on almost any kind of soil, but its rate of growth is most rapid upon those of a sandy nature, while the largest trees and the best bark are produced upon sandy soil with a retentive clay subsoil. This variety grows naturally over a large area of South Australia, flourishing in localities where the rainfall is under 15 in. per annum. Upon the dry open plains of that colony, however, Mr. Brown does not think wattle cultivation could be successfully carried on. The Acacia decureus, or black wattle, is described as being indigenous chiefly to Victoria, New South Wales, and the south-eastern portions or South Australia. It is said to flourish in a sandy soil with clay subsoil, but trees of the largest dimensions are found upon black, alluvial soil. Mr. Brown considers that while it will do well in almost any kind of soil, it will not grow satisfactorily and as a payable crop in exposed situations, or where the annual rainfall is under 15 in. This species is stated to be of more rapid growth, attains larger dimensions, and is sooner available for stripping than the golden wattle, and its cultivation is recommended in the more moist portions of the colony. The bark of this variety is found upon analysis to contain from 29 to 34 per cent of tannic acid, or about the same percentage as in the case of the golden wattle. The Acacia dealbata, or silver wattle, grows well in comparatively moist districts, but as its bark is weak in tannic acid, its cultivation is not recommended. Of the Acacia saligna, or the wattle of Western Australia, little is known, although its bark is said to be as rich in tannic acid as that of the black or golden wattle. The two last-named varieties are those which offer the best recommendations for extensive cultivation. Upon the treatment of wattle plantations the report contains some valuable suggestions. The seed, owing to the hard covering in which it is encased, requires special treatment before sowing. It is recommended that the seed be placed in a vessel, and water of 150 deg. temperature, or nearly boiling, poured upon it, leaving it to soak one or two days, and then retaining it in a moist condition until it shows signs of swelling. Seed so treated must be sown in the rainy season and covered with soil. In the case of land where wattles grow naturally the report recommends making enclosures to keep off stock, sowing seed upon patches not naturally provided, cutting all undergrowth and useless trees, and at the end of summer burning off grass and rubbish. After the winter rains the young crop will come up, and when the trees are about a foot in height thinning and pruning is recommended so as to leave the best trees 4 ft. to 6 ft. apart, with single stems. With a little attention in the way of pruning during the second and third years it is considered that the crop may be left to mature itself. When there is a young crop already growing, thinning and pruning as well as the sowing of seed in vacant places are recommended, and allowing the young trees to be drawn up into spindly shape through being too close together is said to be injurious to future growth. As the trees in the case of a matured plantation are in various stages of growth, the annual stripping of the larger trees will make room for the smaller ones. In making new plantations where the plough can be used, Mr. Brown recommends ploughing the land to a depth of four inches, and putting in the seed three or four feet apart, two seeds being put in at each point, and the rows being five feet apart. During the first two or three years it is recommended that the soil should be stirred and kept free from weeds by means of the scarifier, thinning and pruning being attended to as in the cases already referred to. Where the plough cannot be used, it is proposed that a place for each tree be prepared by means of the spade, and the seed covered in to a depth of from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. From January to March is the period recommended for pruning, and for sowing, immediately after the winter season has set in. The report concludes with a statement of expenses and results upon a proposed plantation of 100 acres. The period embraced is seven years; 1,000 trees to the acre are calculated upon, with a yield of 10 lb. per tree, and the estimate is based upon a value of £5 per ton for the bark. Allowing £3 per acre for the purchase of land, £75 for fencing and making apparently liberal

allowances for ploughing, sowing, scarifying, thinning, pruning, shipping, carting, and interest on capital, there is a clear profit shown of £1,108. It must be admitted that the estimates of both yield and price are moderate, and a return of more than £10 per acre over and above interest and working expenses in seven years for poor land would be highly satisfactory. There are extensive areas in the vicinity of the mountain ranges unsuitable for agriculture, and of very little value for grazing purposes, upon which wattles might be profitably cultivated. The Government should undoubtedly utilise in this way those portions of the state forests and reserves where the wattle grows naturally, and holders of poor sandy land in favourable localities should also give careful consideration to this question. It is also probable that extensive areas might be taken up, under the new Land Act, for the purpose of cultivating wattle and producing a tanning material, which, on account of its special qualities, is always likely to command a high price.—*Australasian.*

AGRICULTURE AT THE ROYAL SOCIETY OF QUEENSLAND.

The ordinary monthly meeting of the Royal Society was held at the Museum yesterday week. The President (J. Bancroft, Esq., M. D.) occupied the chair. The honorary secretary announced that no papers had been received by the council of the society prior to their last meeting, but that one announced then had been sent in immediately afterwards. On the motion of the President, it was unanimously decided that this paper should be read. This communication was by Mr. James Pink, F. R. H. S.

On the Hybridisation and Cross-fertilisation of Plants.—After mentioning how little the vegetable kingdom directly ministered to many of the requirements of civilised man, the author stated that this end had been attained by means of agriculture, including the systematic hybridisation and cross-fertilisation of plants; that under natural conditions hybrids rarely existed, and that cross-fertilisation was mainly dependent on insect agency. The sexuality of plants was known to the ancients, who artificially fertilised one plant by pollen from another in order that the produce of trees competent to bear fruit might be secured. In 1787 Thomas Andrew Knight, president of the Horticultural Society of England, first saw the great importance of artificial cross-fertilisation between plants of the same species, and hybridisation between those specifically distinct as means of adding to the available stock of our fruit, vegetables, or florists' flowers. The influence of Knight's discoveries extended to the present day, and the methods which he suggested were still used, and with as great results. In Queensland, however, the systematic use of this formidable process had been little availed of by the agriculturist or horticulturist. Dr. Bancroft had crossed the Isabel with sweet water amongst grapes, and a further cross was suggested of the muscat of Alexandria with the Isabel. It was highly important that these and similar experiments should be continued with a view to developing our local fruit supply. The methods to be employed were of a simple nature, but a knowledge of the organs of flowers and their disposition was necessary for the would-be hybridist. America was quoted as an instance of what might be effected by these processes. Here the first varieties of apple trees planted by the earlier colonists had retrograded, and their produce reverted to that of the familiar "crab." The practice of hybridisation, as taught by Knight, was brought to bear on this condition of affairs, and now America was first in the world both for the quality and quantity of her supply of marketable produce of this description. Their experiments did not rest with the apple, but all other fruit-producers were subjected to them. Thus the European varieties of grape were crossed with their native *Vitis labruscula* with results of the highest importance. Mr. Pink inquired why we should not in Queensland take a leaf from their book, and use one or other of our native species of *Vitis* as they had done with their native rape. The degeneration of our fruit trees—such as peaches and oranges, for example—even in situations highly adapted for their growth, could only be obviated by cross-fertilisation, and it was through the agency of insects, who accidentally accomplished for us this desirable result, that varieties had persisted as long as they had. Hybridisation was not a process the result of which was a matter of chance, but such as could be duly predicted, and, moreover, required results could be brought about by its systematic use. Thus a fruit or flower could be made to combine the properties which were characteristic of their respective parents. It was rare, however, that the progeny of two distinct varieties represented the parents in a perfectly intermediate degree; but the general habit was usually that of the mother or seed-bearing plant, and accordingly the plant of strongest constitution should be selected for the seed bearer. The florist was also indebted to this means for procuring the different varieties of roses, geraniums, or other flowers, and every season demonstrated the fact that the varieties to be secured by this means were practically unlimited. The author concluded by stating that it had been recently demonstrated by Mr. Culverwell that the gooseberry could be crossed with the black currant, and seedlings raised as the result of the cross, and also the strawberry with the raspberry, and that these successes had opened up to scientists a vista of unlimited possibilities, the full effect of which on our orchards and gardens was impossible to predict.

In the discussion which arose Dr. Bancroft entered into further detail on his own operations in connection with the raising of different varieties of grapes, including seedlings from seeds procured fom India. He also mentioned that Mr. Hockings, of Brisbane, deserved great credit for the peaches which he had raised by taking advantage of the results of hybridisation artificially brought about.

One of the most interesting exhibits of the evening was a small sheaf of wheat which the president had brought from one of his experimental farms. He remarked that, with a view to discover a wheat which would withstand the influence of rust, he had procured seeds from all the European wheats, including the varieties from Russia, France, and England; also wheats from Egypt, India, Japan, and America. Out of this large number of samples, all of which had been subjected to experiment, he had only found four which were rust proof entirely, or in a very considerable degree, and of these only one which preserved an entire immunity from it, excepting a single small wheat from Japan. The present sample was one of these four varieties, and was an Indian wheat from Allahabad, long and robust in the straw, with a full ear and well-developed grain. It was remarked that this wheat ripened in the Brisbane and Darling Downs districts a month earlier than any of the European wheats, and that its freedom from rust was due to this fact perhaps rather than to any inherent quality rendering it more especially free. Dr. Bancroft stated also he had tried this wheat for several seasons with similar results, and that if its growth was extended to large areas it would no doubt yield splendid returns, even where a rust-proof wheat was not a desideratum. It was one of those varieties which contributed greatly to the large export of wheat from India. The method of cultivation adopted had been of the most simple description; the land had not been dressed or manured in any way, and the seed was simply sown broadcast and harrowed.

The indifference of Queensland wheat-growers to their own best interests was severely commented upon, especially as exemplified in their apathy in neglecting to avail themselves of the opportunities which had been given them of growing this wheat, amongst others, on a much larger scale than Dr. Bancroft was in a position to do. The experiments in the other colonies in wheat-growing were also referred to.

Dr. Bancroft's remarks were provocative of considerable discussion, relating to the acclimatisation of plants of economic value, and their insect and vegetable pests. —*Queenslander.*

AUSTRALIAN TIMBER.—Of the 10,000 forest trees which probably represent the timber-producing capabilities of the globe, 7,000 or 8,000 would flourish in New South Wales. P. L. SIMMONDS.—*in Journal of the Society of Arts.*

CINCHONA BARK ANALYSES.

We have heard of a good many complaints among Ceylon planters lately as to the vast discrepancy between analyses carefully prepared (on a commercial basis) of their Cinchona Bark in Colombo and those brought to the sales-room in Mincing Lane by the buyers. In many cases, it is said, such London buying analyses are less by 25 to 50 per cent, and a feeling of dissatisfaction in some districts—Dimbula and Dikoya more especially—is said to be rife; but Mr. Ifanshawe of Madulsima, Uva, who has lately returned, tells us that he made a very careful experiment early last year with samples of his bark, drawn from the same lot, carefully mixed and broken up, half sent to Colombo and half to London, and the result was that the home (we believe Dr. Paul's) analysis gave more than double the percentage of alkaloids that the local analysis did! Here on the exact particulars as given by a local contemporary:—

The loppings from a Ledgeriana clearing 18 months old were barked, and the better and older separated from the younger and more papery stuff. Each was thoroughly well mixed under the personal supervision of the proprietor of estates from which the bark was taken—Parsloes and Dagenham, in Madulsima. Analysis in Colombo gave ·69 for the twigs and ·43 for the inferior. Dr. Paul subsequently analysed the same bark and gave the result as 1·91 for the former and ·82 for the latter! This was *three times* as much in the case of the more valuable bark, and *double* as much in the case of the inferior bark, which was certainly a most material and important difference. If the better twigs were placed upon the market here now on the Colombo analysis they would fetch about 11c., if on the London analysis about 40c.

This is decisive as regards Dr. Paul's analysis, and we suppose, if this chemist were the authority in all cases on whom the Mincing Lane purchasers depended, there would be no grumbling.

COFFEE AND TEA CROPS IN CEYLON.

It is cheering in these days to hear of satisfactory coffee crop pickings such as are now being gathered in Haputale where "two-box pickings" are spoken of. In Maturatta again there are decent gatherings, and crops above estimates are talked of. So in Udapussellawa, prospects on some estates are splendid, and one old resident there writes to us:—"I am picking a fine crop and will show a large result, I hope, even with low prices and hard times. The contemptuous terms used with reference to coffee in the public prints are doing us harm. No distinction seems to be made. There are coffee estates doing well, bearing well and paying well, yet one would hardly think so reading the papers." To back this up we have the assurance of Mr. J.F. Walker of Pitaratmalie, Haputale, who has just left in the S. S. "ClanMacpherson" on a trip home, that he expects to harvest 7 to 10 cwt. an acre of coffee from those fine properties; but, alas, the same steamer carries home another experienced and respected estate manager in Mr. Joseph Fraser of Matale, who can show how there are no coffee crops at all in the districts north of Kandy this season, the attack of bug having completed the mischief begun by leaf-disease and grub. Cacao is now giving good crops and the high prices reported for the Ceylon products by last mail are very cheering.

Of Tea, the accounts are very good, and the planting goes on apace. Mr. Jackson, the well-known Tea Factory Machinist and Patentee, who is also an old Assam planter, tells us, that, while he is generally well satisfied with the work of planting going on and the growth of the plant, he deprecates very strongly the putting tea on very steep hillsides which he has seen in a few places; he believes that tea in Ceylon is not likely to suffer in the roots as coffee did, for the season that the taproot of the former is so much longer and stronger, feeding far below that of coffee; he is puzzled to realize what may be the outcome of the Ceylon system of pruning once in two years (now becoming common) and plucking nearly all the year round, against the Assam 'rest' of four months; but so far he has seen no evidence of harm unless it be in a certain scragginess of the bush at the top for a time, which he does not remember in India. Mr. Jacksone' Victoria Tea Drier has just been practically worked in the Kadawella Factory and promises to be a great success.

THE CRITICAL STATE OF THE INDIA TEA INDUSTRY

seems scarcely appreciated. We confess to being taken by surprize at the gloomy picture thus drawn by Mr. Cruickshank at the recent meeting of the Indian Tea Association:—

"The proposal to do away with the Bonus system is connected with the question of reduction in expenditure generally necessitated by the low range of values now ruling for Indian teas.

If the present low rates were due to the prevailing dulness in trade, or to defects in the quality of our teas, we might hope that, as business improved, and by means of reforms in manufacture, we should obtain better prices; but although it has been stated that Indian teas have deteriorated of late, there is good reason to believe that the existing depression is due mainly to the rapid increase in production which is taking place. The consumption has, of course, increased also, but only at a sacrifice in values, Indian teas being now sold in many cases at prices which do not cover the cost of manufacture. Mr. Keswick, who presided at the meeting of this Association held on the 22nd February 1882, congratulated members on that occasion on the improvement which had taken place in the tea industry during the previous year. Payments of dividends for 1880, he said, were the exception, but for 1881, they were the rule. We cannot say this now. For the past year I expect dividends will again be the exception. Some interesting particulars with regard to the results of the working of various companies are given in the Annual Statement of the Chief Commissioner of Assam illustrative of the state of tea culture in that province for the year 1883.

Those figures, which are stated to be taken from a list published by the Registrar of Joint Stock Companies, and which, therefore, may be accepted as reliable, show that of 39 Tea Companies which struck balance sheets of profit and loss for the year 1883, 26 companies gave profits, amounting to R5,21,619, or a return of 4·9 per cent. on their paid-up capital of R1,05,53,095, while 11 companies show losses amounting to R2,13,721, or at the rate of 7 per cent. on their capital of R30,34,600. Two companies showed no profit or loss. The net return on the capital of the 39 companies was only 2·2 per cent. The results for the year 1884 are likely to be even worse. I have not been able to obtain reliable information as to the capital invested in tea in Assam, Cachar, and Sylhet, but I think I shall be within the mark in taking the amount at R500 per acre of plant. In the Annual Statement of the Chief Commissioner of Assam previously referred to, the total area under tea cultivation in that province, as ascertained from the returns furnished to Government, is stated to have been, in the year 1883, 161,707 acres under mature plant, and 27,746 acres under immature plant, making a total of 189,453 acres. This area, at R500 per acre, would represent a capital of about R9,47,00,000. If we took into account the sums spent for years past out of revenue on extensions, machinery, and buildings, the amount actually invested in tea in Assam would be

found very much larger, whilst the return now obtained on same is almost infinitesimal. The estimated outturn from the province for the year 1884 as shown by the last returns received by the Association is 48,335,000 lb., or an average yield from the total area under tea of 257 lb., or say 3¾ maunds per acre.

From the brokers' sale lists, I find that the average price realized for the portion of the past season's crop sold in Calcutta is 8 annas 9 pie per lb., and we may take this to represent also the value of the teas sent direct from the gardens to London, where the range of values will not be found, I think, on the whole to differ materially from that current here. Taking then the value of the crop of 1884 at 8 annas 9 pie per lb., and the average yield at 3¾ maunds, in order to obtain a return of say 10 per cent on a capital of R500 per acre, there should be a margin of fully 3 annas per lb. between the cost of production and the price realized for the teas. This would necessitate the teas being laid down in Calcutta at less than 6 annas per lb., and we all know that very few gardens have hitherto done this. The average cost of Assam, Cachar, and Sylhet teas in Calcutta, including charges for selling, is probably about 8 annas per lb. for 1884. In some concerns, the cost of production may have been less, but in a great many cases last season, I fear, it was more.

I have troubled you with these figures as they help to show the critical position in which the tea industry at present stands, and the absolute necessity for a reduction of expenditure in the absence of any prospect of a material rise in prices, which the increasing production that may be expected from the large extensions carried out of late years both in India and Ceylon render very improbable.

Without taking an alarmist view of the situation, it is evident that gardens cannot go on for any length of time producing tea at a cost greater than the price obtained for it, and unless a remedy can be applied, many estates will eventually have to be closed, with disastrous consequences to the proprietors and those employed by them. Attention has for some time past been directed to this subject and efforts made to reduce expenditure, but more remains to be done. Managers have much in their power in connection with this matter. The bulk of the outlay for working a garden is for labour and stores, and upon the careful use or the abuse of these by a manager may depend the question of profit or no profit. Managers must recognize this and act accordingly. We find one Manager making his tea at a local cost of 4 annas per lb., while his neighbour, working under similar conditions, but with less attention to economy and to the judicious application of his labour to the work requiring to be done, runs up his expenditure to 5 annas and 6 annas per lb.

The cost of importing labour has, by the extension of the system of recruiting by garden sirdars, been considerably reduced during recent years. Prices of manufacturing and other stores are also lower, and considerable reductions have been made in the rates of freight to and from Assam. Machinery is still a heavy item of expense, more especially since the introduction of tea dryers, some of these machines, with the frequent renewals they require, alterations and improvements, entailing a heavy outlay on gardens in addition to their original cost. The principal expense on a garden is for labour, and attention must be directed to the possibility of effecting a large reduction under this head. This may be done by a more economical use of the labour available and by getting better work from the coolies so that fewer hands will be required. It is in connection with the subject of reducing the expenditure for labour that proposals have been made for doing away with the payment of a bonus to coolies on re-engaging. I do not know how this practice of giving a bonus originated, but it has now been in force for many years. The system, as the Chairman has stated, is unknown in any other industry, and while entailing an outlay on tea properties that they are no longer able to bear, is of doubtful benefit to the coolies, but hitherto no real effort has been made to do away with it. From the information which the Committee of the Association have been able to obtain, it would appear that upwards of ten lakhs of rupees are annually spent in payment of bonus to coolies in Assam, Cachar, and Sylhet. This represents more than one per cent on the sum of 947 lakhs, which I have taken to be about the amount of the nominal capital invested in tea in these districts, and is probably about half the nett profits realized from the gardens during the past season. In doing away with the bonus I do not think that we should be inflicting any real hardship upon the cooly."

In Ceylon we have a better climate, better communications, and the system of bonus is unknown. Our position, therefore, is much more favourable.

TEA: KACHAR NOTES.

It is a strange fact that, whenever the market falls, the "character" of the tea also declines. But we have always looked on this as one of the broker's "little ways" which "no fellow can understand." However, a well-known London house has stated boldly that Indian tea now-a-days is very inferior to what was made by the good old planter in the good old days, and many papers have wept over our deterioration. This firm also suggests that there is something radically wrong with the manner in which we now wither our leaf—to which process we give too little attention. Now I would not for the world contradict such a high authority, but would it let a little light fall on the subject if I mentioned that one of the partners of this firm was "a good old planter" in the "good old days," who invented a machine to wither leaf, which unfortunately was not appreciated by his fellow-planters? I state the facts—my readers can draw their own conclusions. Though it is absurd to assert that Indian tea is now inferior to what it was from fifteen to twenty years ago, yet it is well that special attention has been drawn to "withering," as it is impossible to make good tea from badly withered leaf, and, although this is an universally recognized axiom, still a good many planters do not calculate beforehand what is the largest space they are likely to need in the season—while perhaps in August a great rush of leaf comes with a long-continued spell of wet weather, and tea houses get filled with leaf that will not wither, and which has to be manufactured anyhow. A poor invoice of tea is the result, followed by a thundering letter from the agents wanting to know why the tea has fallen off so, and fearing the Manager has not "given that attention to his manufacturing," &c.—Calcutta *Englishman*.

THE "SAW TREE."—We attract attention to an extract with further interesting particulars about the *Albizzia stipulata* which will be found on page 924. This Albizzia, like a good many more of the same species, is indigenous to Ceylon; and it is apparently to be freely found in the chenas and forests around and north of Kandy, and we learn today from Mr. J. H. Hadden that he has good reason for believing that he has the tree shading a patch of coffee on Wewelmadde estate, the good bearing qualities of which he has noticed for some time. Three years ago, before the Indian reference to the tree appeared, Mr. Hadden called our attention to the subject, sending us a branch for identification, without, however, the matter receiving attention at the time. Mr. Hadden is of the same opinion as the writer in the *Indian Planters' Gazette* that the benefit conferred is from the fall of leaf, and the surface-manuring so entailed. Experiments in cultivating this tree among tea are, we are glad to learn, likely to be made.

THE OUTLETS FOR INDIAN TEA.

Standing as it does for the greater part by far of the capital embarked in the cultivation of tea, the Indian Tea Association deserves to be listened to with attention when it presents its annual report on matters affecting an industry wherein English money is so deeply concerned. So far as mere production goes the statistics of the past year are not discouraging. The crop is reckoned at 62½ million pounds, against 60 million pounds in 1883: in other words, about twenty-eight thousand tons of tea, almost the whole of which is available for export, the requirements of India being quite inconsiderable. Ninety-eight per cent of the quantity exported goes to the United Kingdom, and the balance chiefly to Australia. The efforts which were made five years ago to introduce Indian tea to Australians, through the medium of tea-shops at the Melbourne and Sydney Exhibitions, had as their consequence an extraordinary opening of the Australian market for the time being followed by a temporary glut, which we may now hope is passing over, for the exports to Australia have begun to rise again after falling very low in 1883. There are reasons, however, for declining to nurse any extravagant hopes of the Australian market. The population of the colonies is not yet sufficient to take off any large proportion of the tea which now finds its way to England, and it will probably not be long before Australia begins to grow tea for herself. Already coffee is being tried in the tropical districts of Queensland, and Mysore and Ceylon warn us how easily coffee-planters can turn themselves into tea-planters. Coffee is grown in Australia together with cocoa and India-rubber, the caoutchouc trees giving shade to the young plants, and in this way as much as three and four hundredweight of coffee, worth 1s 6d the pound, can be got per acre in the third and fourth years of cultivation. Speculation is rife as to the locality best suited for tea, and some of the river-valleys on the eastern coast, between 15° and 20° of south latitude, seem to be destined for the experiment. It is, indeed, evident that Indian tea will henceforward have to compete with an increasing number of rivals. Ceylon, at our own doors, is already a formidable competitor. Three years ago tea in Ceylon was spoken of as an experiment, and now we have an export of 2½ million pounds, with every promise of rapid expansion. We hear of tea cultivation in Fiji, and the French have opened plantations at Noumea, from seed which the Indian Government has procured for them from Assam gardens—another exemplification, perhaps, of the poetic parable of the eagle whose own plume feathered the arrow that laid him low. In Natal it has been proved that tea can be made for sixpence the pound—a rate quite as cheap as the average cost of production in India, while eightpence a pound, it is said, will pay the cost of exportation and leave a profit.

The first desideratum for Indian tea, therefore, is a new market in some part of the globe where we shall be secure against competition. For there is no reason to believe that the expansion of the English market will even keep pace with the increasing production of tea all over the world. Fifty years ago the total imports of tea into England amounted to 30 million pounds: they are now 60 million pounds from India alone; yet if we suppose the same rate of development to continue for another fifty years, who can help seeing that it will be more than covered by the produce, perhaps, of countries where tea is not grown at all at present, and that if India is to enjoy the advantage of even a part of the increased demand, it must be on the condition of diminished cost of production? A new market, then, is the thing really wanted in order to save Indian tea from its precarious position. The Tea Association seems to indicate, but in a doubtful and half-hearted manner, that something might be done towards discovering such a market in Tibet. The subject is not a new one, nor has any fresh light been cast upon it recently; but old facts have once more been brought to the front by new men, and it is worth while to state what they are. The Deputy Commissioner of Kamrup is obliged to pay an annual visit to a triangular promontory of British territory in the Bhutan hills, which we have held as a material guarantee since the last Bhutan War, and which is known to us by its Assamese name of Dewangari, but the Bhutias call it Dongsam. Hither the Bhutias come, to the number of some thousands in February and March, to exchange blankets, lac, and wax for the rice and brass and copper ware of the plains. Moving among them with an observant eye, the Deputy Commissioner noticed their universal practice of solacing themselves at the close of the day with large draughts of tea, and on asking for the commodity in its merchantable shape, he was shown the veritable brick tea of China, in blocks weighing about 4½ pounds, wrapped in paper bearing the Chinese mark. Such a block in Dewangari was worth four rupees, though the tea is of the coarsest description imaginable, and seems in fact to consist entirely of prunings, the leaves being large, old, and stringy, and intermingled very freely with twigs. An article of at least equal goodness could be prepared by Assam tea-planters from the refuse of their gardens, and offered for sale at Dewangari for a price considerably less than a rupee a pound. The Tea Association, however, to whom one of these bricks was forwarded with this suggestion, do not take a very hopeful view of the matter. Apparently the making up of the tea in the brick shape is just one of those little departures from established custom which it is so difficult to get effected in trade, but which when effected often produce such surprizing results. Mr. Cooper and others have told us how the thing is done; there are three kinds manufactured, and that which finds its way to Dewangari seems to be the poorest of the three; the leaves and clippings are trodden into a pit, and there allowed to ferment thoroughly, ricewater is then added to give the mass a glutinous consistency, and it is compressed in wooden moulds with sliding ends held down by a lever, considerable force being exerted so that the heterogenous mass coheres closely after drying; the last process is the wrapping in paper. The tea thus made has to be carried 200 miles over frightfully precipitous country on the backs of coolies, after which the cost of carriage is almost done with, for its subsequent passage through Tibet on the backs of yaks that graze as they go is extremely inexpensive. Still it costs a rupee a pound at Dewangari, while the stuff it is made from is absolutely worthless in tea-gardens thirty miles from that place. Any planter who chooses to amuse his leisure by the experimental manufacture of a few bricks can entrust them to the Deputy Commissioner of Kamrup for sale or distribution among the Bhutias, and it seems difficult to believe that they will prove so fastidious as to persist in refusing a cheaper and better article, because it may not exactly correspond in all points to the tea they get from Tibet. The Bhutias are not without some experience of Assam tea already, and the fault they find with it is that it is deficient in twang; it does not work up into the thick racy mess which is their ideal of a good cup of tea. They make tea by first boiling down a portion of one of their bricks into a black decoction with an intolerable flavour of bark and tannin; the next step is to mix this tea-porridge with butter; boiling water is then added, and the resultant liquid is churned furiously for ten minutes in a bamboo churn with a lid on, till it is worked up into a yeasty mess, when it is considered fit for drinking. But if ordin-

ary Assam tea does not come creditably through this course of treatment, it does not follow that Assam prunings would not do so ; and when we remember that the experiment would cost nothing, it seems to argue a want of enterprize on the part of the planters of Kamrup, if this opening for their waste produce is offered to them year after year and no advantage is taken of it. The case is peculiarly one where the initiative can usefully be taken by official agency, and the Agricultural Department in Assam is now making fresh endeavours to bring the wants of the Bhutias into contact with the tea industry of that province ; but of course nothing can be done without the co-operation of the planters, on whose part some degree of inventiveness and enterprize is absolutely necessary if a beginning is to be made at all.

The mere trade with Bhutan, of course, is an insignificant matter. The whole population of the country probably falls short of one hundred thousand souls. But Bhutan is the medium of communication with Tibet, and Tibet consumes about six milliond of pounds of Chinese tea annually, and would consume as much more if it could be got. Without in any way trying to force our trade on Tibet (than which a greater mistake could scarcely be made), common sense demands that where we find articles of Tibetan merchandise offered for sale in the markets of Assam, we should give our own produce in exchange. It is not necessary to enter into any negotiations about the right of passage of Indian tea through Bhutanese or Tibetan territory, or to begin any correspondence with a view to disarming or overcoming Tibetan or Chinese exclusiveness. It is not by diplomatic pressure nor by commercial or political missions that intercourse with Tibet is to be opened up, but by simply placing in the hands of the Bhutias, who act as our intermediaries in this matter, the one commodity which both they and the Tibetans chiefly desire, in that peculiar form which is familiar to them and which they are prepared to appreciate. We may safely trust to the Bhutias to carry our tea to Tibet, if they approve of it themselves. It has been proved, as we think, satisfactorily that, even supposing political jealousies removed and the roads thrown open, the direct exportation of tea from Darjeeling or any other Indian district to Tibet would be costly to a prohibitive degree. But we know as a fact that the Bhutias carry on a trade with Tibet, and are only too glad of any opportunities for its extension, because they make it very well, though we could not do so. We need not, therefore, trouble ourselves with calculations as to the comparative cost of placing Indian and Chinese tea on the Tibetan frontier, as if the question were one of coolie-hire at so much per maund for so many hundred miles of road. The Bhutia traders will assuredly find means to offer Indian tea to their Tibetan customers at remunerative rates, if we can first induce them to buy for themselves. It is, indeed, scarcely credible that the present anomalous state of things can go on indefinitely, with Indian tea-planters complaining of overstocked markets, while their nearest market, and one of their largest, is shut against them, not so much by any deliberate policy of exclusiveness, as by a want of adaptation between the article produced on Indian tea-gardens and the requirements of the Tibetan tea-drinker. We cannot believe that such a difficulty as this will prove insurmountable. The Indian Tea Association itself reminds us that much greater obstacles have been overcome by the tea industry in Assam. Turning back fifty years to one of the first reports on the manufacture of tea and on the extent and produce of the tea plantations in Assam by Mr. C. A. Bruce, the reputed discoverer of tea in the Assam Valley, who then held the office of Superintendent of Tea Culture, we see how humble and tentative were the beginnings of an industry which has since assumed such magnificent proportions, and created, as it were, the prosperity of a province. Mr. Bruce was then engaged in reconnoitring tracts of indigenous tea-plant in an unexplored country which did not even belong to the British Government, and his utmost ambition was to produce from ten such tracts 35,000 pounds of tea. The jungles through which Mr. Bruce wandered are now orderly and populous tea-gardens, and his 35,000 pounds of tea have been multiplied a thousand fold. To the same energy which has brought about these results we may look for a timely occupation of all the markets that are necessary to the maintenance and advancement of the great industry of which he was the pioneer. The winning over of Tibetan custom ought not to prove an impracticable task to the enterprise and perseverance which have achieved the reclamation of Assam.—*Pioneer.*

THE "SAW" TREE.

ALBIZZIA STIPULATA.

It is now some fifteen years or so since the beneficial influence of the Saw tree was first suspected.

In the good old times, however, there was less need to look up any matter of this kind, and hence the knowledge gained by a few was not utilized. As prices fell and dividends became small by degrees and beautifully less, the subject received more attention and means were taken here and there to plant these trees among the tea, with a beneficial result, as at Ahmguri, by Mr. J. Buckingham.

As a rule, the tree grows with a fairly clean stem 20 to 30 feet in the bole, forking frequently into two nearly equal branches, carrying little or no foliage. The spread of these branches is generally considerable, giving a flat topped appearance, and the ascending axis, so conspicuous in the Simol (or cotton) and the Roghu (or kodom) is quite absent, and the general aspect at a distance is not unlike the letter Y.

By some persons the benefit derived from the tree has been attributed to "shade," but this can hardly be the cause because the mass of foliage compared to the size of the tree is small, and the leaflets are small and scattered, giving indeed very little real shadow below. A feature by which the Saw can be recognized is that which gives the specific name, *i.e.*, the deep red, or at times green stipules, which in young shoots are large and arise at each side of the leafstalk, and which eventually drop off. The bark is grey and marked by horizontal furrows, not unlike the Siris, and is half-inch thick reddish inside. The sapwood from three to five inches thick, is white and soft, decaying rapidly if exposed to weather. The heartwood of old trees on the contrary is lasting, and though light, stands exposure. It is coloured a brownish purple irregularly waved with lighter streaks, and dark strings. Like the heartwood of all the group to which it belongs, it is very *cross*. Saw is a remarkably light wood and it is also very lasting.

It seeds profusely in January or February, the seeds being little discs about one-eighth to three-sixteenths of an inch across, eight or ten in a flat pod half-an-inch wide, by four inches long, at first purple color, and drying to a drab. The Saw has no distinct and conspicuous tap root, the absence of the descending axis repeating the absence of the ascending. It has however large laterals that dividing, more or less repeat the growth above ground, though apparently having nothing peculiar about them, as likely to facilitate drainage more than would the roots of most other trees. It is difficult to see how the idea arose that the benefit due to this tree in particular must, or may be due to drainage, as this benefit is at times conspicuous on the very *edge of a khud* or steep slope, where drainage is naturally at such a maximum as to completely obscure any drainage effect due to tree roots, however, favourably inclined that way. But it is hardly necessary here to demonstrate that this tree really does improve the growth of tea and increase the outturn per acre, as also the proximity of the other trees as decidedly retard it: the thing is to find out the cause.

By some, the effect is said to be due to "shade," but the majority of planters will at once, and truly, say that

on mature tea, shade is a mistake and retards flushing. It is true that the natural habitat of the tea tree is forest, but under the unnatural conditions in which it is grown in tea gardens, close planting gives the necessary shade to the soil, while the buds and shoots are well exposed to light and air which stimulates growth of foliage, or flushes. Again at certain times of the year, and the larger part of each day, the shadow of the tree at all times rather indefinite actually does not fall around the stem where the benefit is seen, but away from and beyond this particular area.

So that on all accounts, "shade" may be laid aside as a cause. The question of "drainage" has been alluded to above, and is equally unlikely as a cause. Not only is there nothing specially notable in the appearance, position or arrangement, of the roots or rootlets of this tree in particular, but the benefit seen is often at the edge of a khud, as well as on open slopes, or flat land. The mode in which such drainage could act is also never indicated, whether as drawing moisture towards itself or assisting in its escape. Thus "drainage," as we understand the term, seems inadequate as a cause also.

Fertilization of the soil around from the decay of the fallen leaves seems a far more likely cause for the benefit we see, and it is well known that in this respect all trees are not alike. But even here we see peculiarities in the case that make us pause—peculiarities that are very definite and that cannot be evaded tending to shew that this also is not the cause we seek. For instance it seems that long years after the stem and branches of the tree have been removed, and the fall of foliage ceased, the effect of the tree is obvious, and it has been said that the good effect due to fertilization may remain. If the question remained in this stage, it is likely enough that this solution would be accepted and that the fall and decay of the foliage of this tree would be considered the cause of the good arising from it. But it seems that where Saw seedlings have been put out in part of a "tea nursery," the stimulating effect of the Saw was very clearly marked, and that portion far exceeded in vigor and growth the portions where there were no Saw seedlings; as all of these and the tea was but one year old, it is obvious that decay of fallen foliage seems to be also inadmissible.

Lastly, it is urged that perhaps the Saw roots, in assimilating certain substances, may set free others specillye beneficial to tea. Steps are being taken to prove whether the effect is due to decay of foliage, by planting Saw seed with tea in a nursery, every fourth bed having Saw plants. The result is looked forward to with interest. It is also proposed to plant out if possible seedlings of the other trees that are closely allied to the Saw among nurseries, so as to see whether they shew a similar influence. That the Medeloa, has an equally good effect has been observed for some years.

The trees belonging to this group are:—

1. Saw (or Kala Siris), *Albizzia stipulata.*
2. Koroi (or Moroi), *A. Odoratissima.*
3. Hirih, Siris, or Sirisha, *A. Lebbek*, (probably).
4. Moj, said to be *Inga bigemina.*
5. Medeloa, said to be *Acacia Elata.*

—*Indian Planters' Gazette.*

AMERICAN COMPETITION IN QUININE.

The following important information is from the *Chemist and Druggist* of April 15th:—

Our American correspondence shows that very shortly the present condition of the quinine trade both in Europe and the United States may be seriously affected by energetic competition from that side. From figures published in Mr. D. C. Robins' Review of the Drug trade of New York, it appears that during the past six years the importations of quinine into that port have increased nearly five-fold, namely, from 228,000 oz. in 1879 to 1,263,000 oz. in 1884. In the same period the importation of bark has correspondingly declined. In other words, since the removal of the duty on quinine American manufacturers have gradually relinquished their attempts to compete with European works. What are the normal rates of profit on it is a very close secret, but it has seemed evident that they were not great enough to balance the extra duties which Americans have to pay on all their raw materials, on all their utensils, and, consequent on their fiscal system, on all the labour they have to employ. But of late they have shown signs of impatience at foreign domination in this matter. Domestic manufacturers have taken the initiative in reducing prices. A new factory is being set up in New York with plenty of money and experience to support it, and we are confidently informed that not only is it intended to meet the foreign product on equal terms in the great market of the West, but that an invasion of this hemisphere may certainly be relied on. The policy talked of is that they will even sell at a loss on this side with a view of "persuading" Continental and other makers to drop the American markets. We shall behold with equanimity any such competition, as the result must be to benefit consumers and to stimulate trade.

From the notice of Mr. Robbins' report we quotes as follows:—

There is one important feature in this valuable report which may have an important effect on the future of the quinine market here. The falling-off in the importations of cinchona bark has assumed large proportions; for instance, the imports of cinchona bark into New York for the year ending December 31st 1884, were 8,150 bales, against 11,250 in 1883, 28,000 in 1882, 31,700 in 1881 and 32,800 in 1880; while the imports of quinine have been steadily increasing, being for the past six years, each ending June 30th, as follows:—

		oz.			oz.
1884	...	1,263,732	1881	...	408,851
1883	...	1,055,764	1880	...	416,998
1882	...	794,495	1879	...	228,348

It is understood that American manufacturers are resolved to make a vigorous effort to reverse the condition of things indicated by the figures just quoted, and we regret that in this pamphlet Mr. Robbins does not touch on this important point, as, from his association with the only quinine factory in New York, his views would be of interest.

Messrs. Robbins, whom we consulted in New York are one of the two or three firms controlling the Bark and Quinine trade in America.

TELDENIYA, 6th May.—The May number of the *Tropical Agriculturist* to hand: as usual, it is highly interesting and full of valuable information. I hope the Ceylon public fully appreciate it and that its circulation is large and increasing. It is not every colony can boast of a periodical like it. I trust the younger members of the planting community especially value it. I entirely agree with one of your correspondents that it should belong to every estate library.

THE ORIGIN OF CEYLON GRAPHITE (PLUMBAGO).—Mr. W. King of the Geological Survey of India, and one of the most experienced and able of living Geologists so far as India and the East are concerned, is good enough to write with reference to a recent discussion which he has seen in his copy of the *Weekly Observer*, as follows:—"You were all right about the *Graphite*, with that querist 'R.' Your graphite as far as is known occurs only in the gneisses: and those of Ceylon and Southern India are 'as old as the hills,' which age is past counting even in geological time. The gneisses were in all probability sedimentary rocks in their youth: and the vegetable remains they most likely contained became graphite. In those days the vegetation of the land which now exists as the fundamental rock of Ceylon was perhaps as luxuriant as that of Southern Ceylon is now."

Correspondence.

To the Editor of the "Ceylon Observer."

ASSAM HYBRID TEA: ONE STEM OR MANY.

New Brunswick, Maskeliya, 24th April 1885.

DEAR SIR,—I see "Experience" in your issue of the 16th instant, wishes to know where I get my authority for saying, Indian tea planters are in favour of the plan, "to keep the stem of the tea tree or bush clean six inches from the ground by pulling off all suckers and side shoots below that height." I quote from the book on "Tea Cultivation in Southern India and Ceylon," by a Neilgherry tea planter, published by you in 1880, as follows:—

"If the plants are as I advise good hybrids the planter should be very careful to train them all as well as he can do to grow with clean single stem for at least six inches from the ground. This is done by pulling off as they appear all suckers and side shoots below the prescribed limits" (page 25); and further on he says: "In the case of the hybrid or indigenous plant we must look first to the single centre stem, or at any rate, if the plant has been neglected in its earlier days, to the two or at most three stems that spring from the root, and from those give the bush the form we wish it to take" (page 26).

This is so contrary to what is universally practised in Ceylon, in fact to what I have been doing myself, that thought it well to call for discussion on the subject. I have not had sufficient experience to say which mode is the best, though I incline to the Ceylon method, as the great object is to get as much red wood as possible, but there is no doubt the suckers or side shoots will kill out the centre stem, and we are told that this is the object to be obtained. I should of course adopt that which would give the greatest yield of leaf.

I should like to hear the opinion of one who has tried both methods; if there is such an one in the island, I trust he will kindly come forward and give us the benefit of his experience.—Yours faithfully,

A. E. WRIGHT.

N.B.—It is advisable we should consider this matter well now, as it will be *impossible* to revert to the Indian system, when our trees grow up, whereas we could adopt the Ceylon method at any time hereafter.

[It is the fact, we believe, that planters who commenced on the system recommended by a Nilgiri planter have ultimately encouraged instead of eradicating suckers, the object being to get as dense a surface as possible of flush-bearing wood. There is also the fact that in the hot moist climate of Ceylon it is next to impossible to prevent the growth of suckers which in time become additional stems.—ED.]

THE QUESTION OF TEA PACKING, &c., IN COLOMBO.

SIR,—Between you and me, I fancy that *sorting* will continue to be done on the estates; and that all that we can hope for in Colombo is to get the bulking, final firing, and packing.

In the case of small parcels, too small to ship by themselves, some people evidently *do* think it is worth the extra expense of sending them to me for shipment, "T. P." to the contrary notwithstanding.

But, as regards larger parcels, there is no doubt about it; it is cheaper with present arrangements to send them down ready bulked and packed for shipment; and every cent that can be saved in this way to the planter is a perfectly legitimate saving, and one which, as a tea producer, I as much as anyone else am interested in securing.

On the other hand, however, I feel perfectly certain, that, in view of the scarcity of wood in some districts, means will ere long be devised of saving the cost of transport on shooks up and down—and tea lead too. It only remains for some inventive genius to devise the package.

I believe myself that we shall yet see tea coming down in bags. I saw a sample bag the other day at Messrs. W. H. Davies & Co.'s stores, which I think contains the germ of the invention.

The weak point about it at present is the fastening—and the first cost. I gave them my idea as to a remedy for the first-mentioned defect; and, if that can be satisfactorily cured, we may safely leave the adjustment of prices to competition.—Yours truly,

C. W. H.

[If, as we expect, not only Europeans, but the natives in the lowcountry especially, are to become great tea-growers, we may feel sure that, eventually, much of the store-space and of the labour of women and children in and around Colombo, formerly devoted to coffee, will be utilized for tea. Neither "C. W. H.," nor we, meant to write with reference to the present time: let us wait till even the 80,000 acres of tea now growing are in full bearing, and, if, with large sales of tea in Colombo, there is not a considerable change in the present arrangements, we shall be much surprized.—ED.]

TEA PREPARATION AND COST IN CEYLON.

Strathellie, Nawalapitiya, 4th May 1885.

DEAR SIR,—I have today seen "C. W. H." 's letter published in your issue of the 1st of May. He will see from my previous letter on the cost of tea production that (as your correspondent "T. P." has since pointed out) the 5·47 cents per lb. for actual cost here last season of manufacture and tea-house sundries, was *exclusive* of "gathering," the cost of which item was given *separately* by me; neither was "interest on machinery, buildings" &c. included.

As far as I am able to give them in detail, the following are the items comprized in the above sum, which "C. W. H." asks for:—

		Cents per lb.
Rolling and firing	...	1·84
Sorting and packing	...	0·50
Boxes (20 lb. to 100 lb. nett) lead, hooping and solder for ditto.	...	2·83
Sundries, watchman, &c.	...	0·30
Total as above,	...	5·47 cents.

—Yours faithfully, ARTHUR E. SCOVELL.

JACKSON'S VICTORIA TEA DRIER.

Strathellie, Nawalapitiya, 6th May 1885.

DEAR SIR,—I yesterday witnessed, with some others, the working of Jackson's Victoria drier (class B) just erected at Carolina factory.

Mr. Jackson has so far given us the best roller, and I should now say that the above machine will prove itself the "Excelsior" amongst driers. The principle (automatic in action combined with a constant draught of *fresh* heated air) appears an excellent one. Reliable data as to capacity will be obtainable after the machine has been in full work for some time. The quality (appearance, "nose," &c.) of the tea I saw turned out was equal to the result of the "Sirocco" and superior to that of "Kinmond." Jackson's drier, like his roller, is a fine specimen of Marshall & Sons' work: *made to last*.—Yours faithfully, ARTHUR E. SCOVELL.

ANALYSES OF CINCHONA BARK.

SIR,—Referring to your observations (page 921) on the analyses of bark made locally and in London, nothing can well be more important than accuracy in such matters, both from the buyer's and seller's point of view. It is evident that Dr. Paul has the confidence of consumers at home, as I know he has of the profession. And there is no reason why he should not have, because, possessed of a laboratory fitted with every modern and necessary appliance and apparatus, in constant practice, with the purest chemicals and an assured process, results cannot be doubtful. Well mixing will ensure an even sample in great quantities, but, when only a very small selection is made for analysis, it is not easy to get a fair sample of the bulk. I do not know what practice obtains in Colombo, but I do not doubt the analyst knows his business and draws his samples accordingly. If this be done the same as in London, there should be no discrepancies in the result. But in lots of bark made up from many fields and trees differing greatly in age and soil, it is not a matter of surprize that the samples selected for analysis differ in themselves, thus causing a difference in the result.

There are several ways of making the analysis, but I presume there is more than one analyst in Colombo? Any grower with a large lot of bark, anxious for an accurate analysis, should himself take two pounds at least from the bulk (fairly representing it) dry it, pound it and sift it *all into a fine powder*, which is *then* a thoroughly mixed sample. One part of this powder he should then send to one analyst, and the other part to another analyst: their results *should be practically identical.*

I do not suppose Dr. Paul *himself* analyses the many samples sent to him. At all events, the writer was once a student in a chemical laboratory to which many samples came of manures and soils. Equal parts were given to assistants or advanced students, by the principal, and they, working separately, had to produce identical results.

This check also would effectually detect the faulty analysis, if a part of the same powder given to the Colombo analyst were sent home to Dr. Paul. Z.

TEA CULTIVATION, PREPARATION AND DISPATCH IN CEYLON.

8th May 1885.

DEAR SIR,—I am obliged to Mr. Scovell for the particulars of tea preparation and cost in your issue of 6th inst. Of course, I was aware that "gathering" was not included in the 5·47. "T. P." 's misconception arose through a misprint of the word gathering for sorting. I observe that sorting *and packing* only cost Mr. Scovell 50 cent per lb.; whereas "S." pointed out a saving of ·50 cent that might be obtained on sorting alone, by this operation being done in Colombo instead of on the estate. Evidently, however, it would not be attainable in Mr. Scovell's case. His packages too are very cheap, almost incredibly so, if there was any large porportion of small packages. All this points to the conclusion that there must be some other grounds than mere cheapness to make it worth while for large establishments to resort to Colombo. As you very justly point out, however, with 80,000 acres of tea in full bearing, and increasing scarcity of wood ready to hand, circumstances may be greatly modified in the near future. It would be interesting to know if Mr. Scovell's packages were made on the estate. I mean the boxes.

I send you herewith a sample of wood, in which some tea came to me to be repacked, as the chests were all in the state of this sample. Not only was the wood as you see it, but the leads were also eaten through and through. This wood, whatever it is, should evidently be avoided; and all the more so because at first sight it looks particularly adapted for the purpose.—Yours faithfully, C. W. HORSFALL.

[The wood is—as far as "W. F." can make out—"one of the inferior *Kinas* (Callophyllum species), but at any rate it is a very perishable and worthless wood, and most unfit for tea boxes. Perhaps, too, it was not properly seasoned. There certainly should be a set of the timbers of Ceylon in the Museum for reference on such occasions as this, to be able to identify each kind of wood. The carpenter calls it Wallu-kina, and this is Callophyllum Moonii or C. Walkerii, but see Thwaites's 'Enumeratis.'" We think it well as a help to tea-planters to quote all the varieties under "Callophyllum" as follows:—

CALOPHYLLUM, Linn. Nom. vulg. "Keena-gass," "Waloo-Keena-gass."

1. C. WALKERII, Wight; Hab. Nuwara Eliya, Adam's Peak and other of the most elevated parts of the island.

An oil is extracted from the seeds of this and the other species of the genus, which is used for burning.

2. C. THWAITESII, Planch; Hab. Var. *a*, Ambagamuwa district. Var. B, Hinidoon Korale, at an elevation of 1,000 to 2,000 feet.

The leaves of this plant vary much in shape, and the foliage often strongly resembles that of the preceding. In very young plants of what I believe, to be this species, the leaves are lanceolate or cordate-lanceolate.

3. C. TRAPEZIFOLIUM, Thw,; Hab. Hunasgeriya district, in the Central Province, at an elevation of 4,000 to 5,000 feet.

4. C. CUNEIFOLIUM, Thw.; Hab. Medamahanuwara, at an elevation of 3,000 to 4,000 feet.

5. C. INOPHYLLUM, Linn.; Hab. Hotter parts of the island, up to an elevation of 2,000 feet. Nom. vulg. "Domba-gass."

6. C. TOMANTOSUM, Wight; Hab. Central Province, at an elevation of 3,000 to 5,000 feet; common.

The timber of this abundant tree is valued for building purposes, and the seeds are collected in considerable quantities for the sake of the oil they contain, which is called "Keena-tel."

7. C. BRACTEATUM, Thw.; Hab. Saffragam district, by the sides of streams, at no great elevation. The bracteated racemes, much smaller flowers, and oblong fruit, abundantly distinguishing this from the preceding species.

8. C. MOONII, Wight; Hab. Forests in the district between Galle and Ratnapura; not uncommon. Nom. vulg. "Domba-keena-gass."

9. C. BURMANNI, Wight; Hab. Hotter parts of the island, at no great elevation.
—ED.]

NO. II.

8th May 1885.

DEAR SIR,—With my last letter on tea packing in Colombo *versus* estate, I intended to let the discussion drop as far as I was concerned in hopes that like every such wild scheme it would die a natural death; but I see in your issue of 5th that "C. W. H." is still hankering after the idea of bags,, as a means of conveying tea from the estate to Colombo." "C. W. H." admitted the truth of what I pointed out, that there would be considerable danger from coarse leaf getting mixed with the finer sorts by using pressure in putting unsorted tea in chests or boxes: in the case of bags pressure would be a necessity. Look to it how one may, the same difficulty arises, the tea must be pressed down, in other words broken, to fill the bags properly; if the bags are filled without using pressure, the tea will be broken more or less each time the bag is thrown down, and in both cases the squeezing that the bags would be subjected to at the hands of the cartmen would have the same effect, breaking and consequently mixing the inferior with the finer grades of tea.

Notwithstanding your advocacy of this system* and "C. W. H." 's attempt to prove that it would be feasible, not one redeeming feature has been shown in its favour; but, on the contrary, from whatever point of view it is looked at, increased cost to the producer appears prominently before us, and side by side with it division of responsibility, loss from re-weighing and final firing, creating confusion in accounts, loss by bursting of bags en route, loss from pilfering and mixing by cartmen and damage by rain when after atime the waterproofing becomes worn off the bag.

No, no, Mr. Editor, you must not saddle the already overburdened planter with the maintenance of the Colombo mills. They have had their day. The annual export of coffee is rapidly decreasing that for next year† will certainly be under 200,000 cwts., probably will not much exceed 150,000 cwts., enough perhaps to give full work to three of the largest mills, and merchants will have to submit to the inevitable and turn their attention to purely commission business. I suggested in a former letter that some other use might be devised for the empty stores and barbacues. Could not a Skating Rink Company be promoted to take over a few of them? A Public Hall Company to purchase one in the Cinnamon Gardens, another or perhaps two in the neighbourhood of the Pettah? A few more might be utilized for the erection of baths now that Colombo will so on be provided with an abundant supply of water. S.

TEA FACTORIES: OLD RAILS AND CHARCOAL.

Wattegama, 9th May 1885.

SIR,—In your issue of the 8th, "Planter" asks what is the average length of old rails of the Ceylon Government Railway. Most of the rails are 21 feet in length, and I believe two of them would be equal to the strain that an 18 inch pillar of masonry would stand, and, if you wanted three rails, you could take off half the flange of two of them and bolt all together, or four rails even with half flange taken off each rail; and if "Planter" wants any further information as regards what can be made from old rails, I think Mr. H. K. Rutherford would be the man to apply to, as I saw some good bridges that he made from old rails eight years ago at Gampola, and the same can be done as regards tea-houses. Old rails are sold at £4 per ton, and about five rails go to the ton and a few tons would go a long way with a tea-house for pillars, beams, ties, and so on, and would last for ever.

As regards charcoal, if "Planter" will cut his wood in lengths of about six inches, make a pile of it and cover with earth, leaving a hole at the bottom to set light to it and a hole in the top as a vent for smoke and so on, until the whole is well alight, and then cover up completely, he will get charcoal. —Yours truly, RUST.

THE ROCKS OF CEYLON: INTERESTING AND ACCURATE INFORMATION.

Colombo, 12th May 1885.

DEAR SIR,—I would remind your correspondent "A Geologist" that the rocks of Ceylon belong almost entirely to the gneiss and mica schist groups, known also as the azoic or non-fossiliferous system. This distinction, however, rests solely on negative evidence, no remains of life having been as yet discovered in these rocks. They are also known as metamorphic, a name referring to their mineral characteristics, and implying that the original structure of the rocks has undergone a change.

Primary limestone is found in parts of Ceylon, notably between Hakgala and Wilson's Bungalow, and between Badulla and Taldena on the old Batticaloa road, but it is a highly crystalline rock devoid of fossils.

Quartz rock occurs largely in many of our planting districts, notably in Madulsima. Mica schists and talc schists are not uncommon: very perfect specimens of the latter can be seen near Migahakeula on the old Batticaloa road. All these, however, belong to the same system of metamorphic rocks in which, as I stated before, no fossils have yet been found. Being however distinctly stratified rocks originally formed by the action of water, it is possible that remains of life or plants may be found in these rocks.—Yours faithfully, GRANITE.

* This is a curious example of jumping to conclusions; we "advocated" nothing of the kind; we "speculated" as to what the future might bring about and asked "C. W. H." for his opinion, and so we are both criticized as if we were urging planters to make a change!—ED.

† "S." talks of "next year": we refer to *five years* hence, when 80,000 acres at 400 lb. each should be sending 30,000,000 lb. of tea through our port: a good deal no doubt sold locally and dealt with finally in Colombo.—ED.

BOGAWANTALAWA, 9th May.—We are at last having what appears to be the little monsoon, wet, thundery afternoons, and stuffy, hot mornings. Coffee is looking well, and in the lower end of the valley crops will exceed those of last year. No signs of leaf-disease. Tea is doing wonders. On one field of 40 acres, 20 months old, topped only 3 months ago, the yield of the 4th plucking is 36 pounds leaf per acre! What do you think of that! The immediate necessity for large factories and machinery has given us a sudden but pleasant shock. I am pleased to see Colonel Money is taking notice of the increased duty on tea. If it passes, the producer will suffer most. Mark my words! [No fear of a duty on tea now.—ED.]

NOTES ON PLANTING AND PRODUCE.—Several letters have reached us upon the subject of a proposed duty on tea. "Common Sense" writes:—"All should protest against this proposed tax. It is monstrous that tea, a necessity for the poor and a harmless drink, should be taxed at such an absurdly high rate, it is difficult to perceive. It this increase is carried out it means 100 per cent on Chinese, and 75 per cent on Indian teas, *i. e.*, on the prices they now fetch in Mincing Lane! The increased tax will all be paid by the consumer, no part by the retailer. The 6d duty is already out of all proportion to the value of the article." Anglo-Indian writes:—"Apart from other considerations a tax on tea would be a blow to India." Tea culture in Hindustan has made rapid progress during the last twenty-one years. In 1864 the consumption was little more than 100,000 lb. It reached last year quite 60,000,000 lb. Would it not be most impolitic and inexpedient to put heavier shackles on this important industry, to check the expanding output of extending gardens.—*H. & C. Mail.*

THE ASSAM TEA INDUSTRY.—We quote as follows from the general summary prefixed to the report on the administration of the Province of Assam for the year 1883-84:—"The total number of tea gardens on their register is 1,023, of which 590 are worked by Act coolies, 224 by coolies not under the Act, and 299 have no resident labourers, but are worked by the inhabitants of the neighbouring villages. These gardens occupy 923,000 acres, but only 167,700 acres were returned as occupied by mature tea-plants in full bearing. The tea crop of 1883 amounted to 46 or 47 million pounds, or about 290 pounds per acre; it was an average crop, and much the same as that of 1882, but the area under tea having increased, the outturn was larger by about 2 million pounds. The average cost of cultivation may be roughly set down as 6 annas per pound, and the average price obtained in Calcutta, after payment of freight, at 8 annas. This does not leave a large margin to cover interest on capital, which may run as high as R1,000 per acre." —*Indian Daily News.*

AUSTRALIAN STOCK FOR INDIA AND CEYLON.

Every one interested in the expansion of the Australian trade with India, and especially in the export of stock to this country, will be glad to hear that Mr. Thompson of Sandridge has built a steamer named the "Bucephalus," expressly for this purpose, and which, when the last mail left, was loading a cargo of horses, as well as cattle and sheep for our market Mr. B. Gray, who was once upon a time a large exporter of horses to different parts of the world, was invited by the owner of the vessel to inspect it, and pronounce his opinion as to its suitability for the purpose. The following is the result of his inspection. He says:—"I found a steamer capable of carrying 350 horses, or a larger number of cattle, with some passenger accommodation. I had not the slightest idea that there was such a vessel afloat. Some 18 years ago I sent several shipments of horses to Colombo, also a few cattle and sheep to my friends, Messrs. Rudd Bros., of that port, and although I spared no expense in procuring the best ships and fitting them in the best manner, the losses on each shipment were a heavy drawback on the transaction. I think I am safe in saying that in nearly all shipments to India and Mauritius since that time, heavy losses have been incurred, of course, materially interfering with the trade. I was much pleased, therefore, to find that in this steamer there is everything necessary to minimize these losses to an extent quite marvellous compared to the days I refer to. The space allotted between decks to each horse is 3 ft. × 9 ft., with 10 ft. in height, and some 18 ft. from head to head in the rows. The hatchways are from 20 ft. to 24 ft. long, 10 ft. wide, and there are four of these, supplying a current of air equal to any requirement, while 50 horses can be placed on deck in equally comfortable quarters, for the gunwales are some 5 ft. high, and these are supported by iron arches, over which an awning can be thrown, thus protecting in all weather, furled in fair weather. All the fittings are of the most substantial kind, the floors battened and filled with sand between, and these are cleaned every two days, making all comfortable. The food is supplied in movable mangers to which the men have easy access. Quite a novel feature in our export of stock to India were a large number of dairy cows that are being sent up for the purpose of establishing a herd of these cattle in the hill countries, and it appears to me that it will be a most successful venture, for there can be no doubt of the superiority of such stock over the native breeds, both as milk and beef producers, and comfortably lodged as these are in this fine vessel, I feel sure they will be landed in as good condition as when shipped. There was also a small lot of sheep, but I fancy those selected, being cross-breds, are not the animals suited to that climate; however, it will test the practicability of sending sheep to India; in fact, the whole shipment is one of great import to Australia, and such an enterprise as building this vessel lays all stockbreeders under a great obligation to her owner, and I see no reason why live stock could not be carried in such steamers to the English market, especially from northern ports where such large tracts of country are being stocked. The facilities for putting stock on board this vessel are so great that a whole cargo can be walked safely on board in some three or four hours, and transhipped with equal facility. The lines on which she is built strike the most unnautical to be such as would ensure speed and safety, and Captain Currie told me her record was 12 knots an hour. No doubt a good deal of the success of the trips of this boat is due to the sterling character an her commander, who strikes one at first sight as or thoroughly practical seaman, with his weather eye always open. The horses which form the chief cargo this trip, are the property of Mr. Learmouth, well-known in the Indian trade, and I think Col. Williams must be more critical than he is if he rejects any of those I saw waiting to go on board. They were also in splendid condition, speaking volumes for the pasturage they had come off, and I shall be much disappointed if this does not turn out one of the most successful ventures of stock that Australia has shipped; and have only to add that my description falls short of what might be said of so interesting a subject to stock owners."—*Indian Agriculturist*, 28th March.

PLANTING REPORT ON UVA, CEYLON.

BADULLA, 6th May.

Busy picking here (on many estates two boxes). The weather has been fine for some time past: very hot during the day; fine nights too, with a stiff breeze blowing. One of your correspondents says that Helopeltis does not actually destroy the cacao pods. All I can say is that I have seen the exterior of pods so perforated by the pest as to cause the skin to lose its vitality and become leathery; then the decay of the interior soon follows. On several occasions I have also seen an insect, somewhat resembling a louse, which had taken up its abode in the perforations made by Helopeltis This louse was rapidly deepening the holes, and in one instance had got right into the pod, so that the beans or seeds of the cacao were showing through the skin. If therefore the Helopeltis does not directly destroy the pod, it is the means of doing so indirectly. The discussion about the "devil-bird" in your columns is very interesting: most people upcountry, who have been any length of time in the island, have heard it, but I never remember its identity being discussed till now in the *Observer*. There is no doubt, in my mind, that it is an owl or jar. I heard it on one occasion singing (?) on a moonlight night, in a fig-tree adjoining my bungalow, and certainly to hear the song (?) at close proximity is blood-curdling. I hope not to undergo a like experience in a hurry. On the occasion alluded to I went out of the bungalow on hearing cries (of a human being (as I thought at the time), whereupon a bird flew out of the tree and the cries and groans were heard no more. I cannot say what sort of bird it was:

> "The fell scream of *Howl* may come from an *Owl*:
> The subject attention deserves;
> But certain we are 't is also a *Jar*,
> A horrible *jar* to the nerves.

Glad to hear that Henry Cottam has returned to the island after his extended travels and rough experiences. Hope he will settle down quietly now. He would probably enjoy himself more by so doing than by knocking about the world. You know what Carlyle says: "Oh unwise mortals that for ever change and shift, and say Yonder, not Here! Wealth richer than both the Indies lies everywhere for man, if he will *endure*. Not his oaks only and his fruit trees, his very heart roots itself wherever he will abide, roots itself, draws nourishment from the deep fountains of Universal Being! Sam Slicks who rove over the earth doing 'strokes of trade' what wealth have they? Sam Slick rests nowhere, he is homeless. The wealth of a man is in the number of things he loves and blesses, which he is loved and blessed by! The herdsman in his poor clay shealing, where his very cow and dog are friends to him, and not a cataract but carries memories for him, and not a mountain top but nods old recognitions: his life, al encircled as in blessed mother's arms, is he poorer than Slick with the ass-loads of yellow metal at his back? Unhappy Slick!" Mr. Cottam is the very man to take charge of an experimental garden in Badulla, if one is to be established here, as recently suggested. * He has had much

* Unfortunately we learn that the Uva Experimental Garden, like other good things, is put off till "next year"!—ED.

experience in tropical products; he has studied the subject and takes pleasure in it. Who then could be more suitable for the post than he? He is an old Uva planter too, which fact ought to add to the chance of his getting the berth. I hope he will excuse the quotation from Carlyle which I have written in a spirit of friendliness to H. C., to whom we in Ceylon have frequently been indebted for much valuable and interesting information certaining to countries other than this.

THE WEST INDIES AND PANAMA.

NO. 9.

PORT ANTONIO—STORES AND RUM SHOPS—THE FIRE—ON THE HILL—PORT ANTONIO FORT—BEAUTIFUL VIEW FROM THE FORT—NAVY ISLAND—ANCHORING PLACE OF MEN-OF-WAR—THE WAR WITH THE MAROONS—MAROON MOUNTAINEERS—DOMESTIC ARRANGEMENTS—CHEAP LIVING—REGULAR SUPPLY OF FRESH FISH—THE FRUIT TRADE AND LOADING STEAMERS BY NIGHT—NO REST FOR THE WICKED—MOSQUITOES FROM THE MANGROVE SWAMP—ROUGH TIME OF IT—SAND FLIES—PLANTING COMBINED WITH STOREKEEPING—RUM LICENSE—SPANISH GUNBOATS—TROUBLES IN CUBA.

Iter Boreale Sugar Estate, Annatto Bay, Jamaica,
5th November, 1884.

Port Antonio on the east coast of Jamaica, and in the parish of Portland, is the prettiest little place I have seen in Jamaica up to date: on a fine sunshiny day, the Blue Mountains in the background of the land-locked harbour are grandly picturesque. There are two harbours: vessels coming from the north round Navy Island, and enter a channel made by Navy Island and a narrow peninsula of Port Antonio. At the extremity of this projected piece of land the Fort stands, large guns pointing seaward.

On the south side the little harbour is nearly land-locked, and from some points of view appears to the observer to be a pretty little lake, but men-of-war come in sometimes and stonish the natives by banging off a royal salute. The water is deep and clear, over thirty feet, with abundance of fish, snapper, butterfish, and drummers. All around one are to be seen comfortable villas and cottages surrounded by fruit trees including mango, breadfruit, orange, avocado pear, ackies, roseapple, coconut, cashewnut, fig, aberimoyer, custardapple, jak, jambu, plum, &c., &c., &c. Small banana plantations in bearing and clearings being opened up.

On entering the town of Port Antonio, one is struck by the smallness of the shops and the extraordinary names given to some of the diminutive establishments. For instance, I entered "Beaconsfield House," the property of a respectable cigar manufacturer. His stock in trade amounted to a bundle of leaf tobacco. He made his cigars and found a ready sale for them at 4 for 6d. Every second house in the main street of Port Antonio seemed to be a rum-shop, "licensed to be drunk on the premises." A rum license costs £10, and £12 for retail trade, and £25 for wholesale. So I fancy the amount of mixing must be necessary to clear off the license. It little matters in the long run whether the rum-dealer puts in the water or whether his customer does: anyhow, they both put in a little. In Port Antonio the rum-shops are well patronized by the men, and the linendrapers' shops by the women; the latter make a show on marketday and plenty of noisy bargaining.

Stores there are in plenty, and the prices are very reasonable. My housekeeper made most of my purchases: a perfect work of art in the form of a looking-glass for ninepence, a washing-basin for one shilling, water-jug for one shilling, knives and forks for one shilling the pair, handtowels for sevenpence-halfpeuny, calico for fourpence-halfpenny to sixpence a yard, and muslin sixpence.

Many of the large stores were destroyed by the large fire about a year ago, which like Kingston threatened to destroy the whole town. There is an amusing local song about the great fire, of how a man passing a burning house entered it for the purpose of looking for a sucking pig which he imagined to be well roasted, and he came upon a little roast dog (pronounced "darg" in Jamaican) and commenced to "wire in" not finding out his mistake until too late. A clever fiddler composed the verses to suit a lively tune on his violin, and now every little boy and girl sings it in the street.

There are some nice houses on the hill, in one of which I stayed for nearly a week, Mrs. McBlain's boarding establishment. The views of the sea, the town, and the mountains from the verandahs of some of these houses are very beautiful, and makes anyone like Port Antonio, although if bananas were removed the place would sink immediately into oblivion. The Fort reminds one of the dark days of Spanish rule, when the British took the place. In those cruel days bloodhounds were used to track the absconding negro slave, and the maroons, the descendants of the Spanisb slaves, live in the mountains close by Port Antonio. I was fond of walking through the Fort and thinking of the ancient history of the old place, breathing the sea air, sitting on the ramparts and enjoying the magnificent tropical scenery around me. Navy Island is inhabited, and there seems to be a convenient place for beaching wrecks and repairing vessels. There is a coral reef running out a great way from Navy Island, and I have seen more than one banana cutter come to utter grief on that reef.

Men-of-war prefer the quiet harbour to the outer one where steamers are coming in at all hours of the day and night for cargoes of fruit, the "small craft," schooners, cutters, luggers, &c., bringing fruit from the agents and buyers on different parts of the coast to store it ready for the mail boats.

I suppose the object of the men-of-war's visit is a kind of reminder that no more trouble like that of St Thomas in the East and Morant Bay in Governor Eyre's time (1865) should be contemplated by the inhabitants, who are on the whole a very peaceful and contented lot of people.

Another reason for British men-of-war avoiding the outer harbour of Port Antonio is the fact of a steamer sunk in the middle of the entrance, with only the black funnel and masts appearing above the water to warn vessels coming in.

A firm undertook to raise the illfated steamer after she had been submerged for over a year, and one fine morning, when I was going to the weeders, lo, and behold! what do we see? both a brig and schooner wrecked alongside the steamer, three wrecks instead of one: it is true they raised the steamer, but she went down again, and took the brig with her, schooner falling on the top of all, bottom upwards!

I remember reading a lot about the maroons, but did not know I should ever come in contact with them and have to work them as field labourers. Both men and women come down from the hills and offer their services; they do not, however, like to work with the Jamaica creole or negro, or with coolies from India, but prefer "job work" felling heavy timber. They are good axemen, and with their cutlasses bill down the weeds cleaner than other labourers. They are very quiet workers, though the first to "strike" work if there is any fault to find with the estate or pay in arrear.

In the long war with the maroons, they gave our troops considerable trouble in their mountain home. Even to this day I am informed that the maroon mountaineers are jealous of strangers being amongst them, and that it is extremely unsafe to venture alone into the forest of the maroon country *without a maroon guide*.

Mrs. Watson's nursery maid is a pretty maroon girl "Rebecca," and my washerwoman is another maroon, "Mary Ann King." The boss of my maroon gang was Mr. Bourke, and a very civil fellow he was. Referring to my diary, I find, during the past three months, May, June and July 1884, the creole men and women working on "Bound Brook" seem to have taken a great fancy to me, and are generlly very respectful and work well. Old Moor, the captaa of the "Lime Kiln," is a fine old man and sometimes vei amiing. His grandfather was a maroon of Spanish ny Afr blood, and his father a slave owned by some sugar planter: Moor was born a slave and in 1833 was seven years of age when liberated. The Jamaica negroes celebrate every August by striking work for a whole month in commemoration of emancipation.

I never feel lonely, for the young ladies passing and repassing always have a kind word for their "bookkeeper," "Busha," "Buckra" and "Massa." Everythiug I require is brought to the door for sale, and, if we are out of money, they would wait until payday on Friday night for the balance. Mrs. Parsley who lived in the next cot-

tage to me, about a quarter of a mile down the road, would always have a supply of fresh fried fish, and the bread woman called regularly every morning with smoking hot loaves from a "quatty" to a "fipence," the former 1½d and the latter 3d.

Wednesdays and Saturdays were beef days, and the beef was very good at 4½d per lb. Turtle and crabs often made a change of diet with eggs and bacon or liver and bacon, breakfast on the latter favourite dish being only ninepence, cooked by my housekeeper at her own cottage and brought down to me about 11-30 or 12 o'clock. On Sundays I always gave the housekeeper a holiday by having a piece of beef cooked and served up cold with pickles and enough bread bought on Saturday to last until Monday. A regular supply of chocolate sticks were bought every Saturday by Miss Angelina Doyley of Norwich, the nearest village, and my morning chocolate boiled in goats' milk was a grand institution the goats' milk was obtained from Mrs. Sarah Parsley for a "maccaroni" a week. A mac or maccaroni is an English shilling. Beef is a "bit" per pound, a "bit" being fourpence-halfpenny.

Young coconuts were in great request during the past three hot months, June, July and August, the drinking-water being often doubtful. Young Parsley brought me a "gourd" of water from the washerwoman's pool near the "Hog Pen," and it actually tasted of the blue mottled soap!—hence my purchasing young drinking coconuts from the Norwich girls as opportunity offered at 3d for four nuts.

Mr. Nash, the "Tenant Ranger" or collector of rents from the cottagers and small farmers on the Bound Brook estate, often killed sheep at "Shotover" and sometimes a fat sow; therefore Port Antonio is a cheap place to live in: enough yams and cocos can be bought to last a week for a "bit" and a "quatty" or 6d.

Miss Alice Doyley sold bread, fried-fish, gingerbread and gingerbeer, all on reasonable terms, and her cigars at eight for one shilling were cheaper than the "Beaconsfield House" weeds.

Port Antonio is the Batticaloa or Puliyantivu of Jamaica, the Eastern Coast, and, like the Eastern Coast of Ceylon, famous for its bays and fine harbours coconut cultivation and fruit of every description. Many people engaged in agricultural pursuits, and fishing. Fish is sometimes plentiful, good, and cheap: amongst many kinds, the "snapper", rock fish, sun fish, angel fish, butter fish, mullet, drummer, The mountain mullet is considered the most delicious of all.

Living is cheap in all Jamaica, except at some of the private boarding-houses, where one is charged part of the house rent, taxes and attendance, and charged from 5s to 10s per day for sometimes indifferent fare. Housekeeping is to be preferred, especially when living in a free house and a housekeeper engaged for a dollar per week. The people themselves live principally on yams, coco yams, mango, breadfruit, boiled and roast bananas and plantains, with salt fish of kinds. Saturday and Sunday they treat themselves to a little more substantial fare, and a pint bottle of beer or porter may be often seen peeping out of the painted tray, when the wind blows up the corner of the towel supposed to conceal it. Our creole men are fond of "old Jamaica" rum, and get tight sometimes.

Nash and Carpenter, the two Rangers, are very steady good fellows and have not given me any trouble since my arrival. Simpson, Henry, Edmond, Bourke, Niel, Lewis, Parsley, Hartley, de Costa (mason), Deckers (carpenter), and Gregory (carpenter) with many others were good working men and always willing and obliging. I mention the above because people making flying visits to the West Indian Islands, particularly Americans, condemn "Quashie" as a lazy, good-for-nothing, cheeky nigger, who "yams it" under his own breadfruit tree and does not care to call Her Majesty Queen Victoria his aunt. It is true he is somewhat independent, and in a few cases very cheeky, but not vindictive, for he will apologize next day and perhaps bring a "peace offering" in a shape of a basket of good mangoes or a soursop fruit, and expresses great sorrow that he got so "vexed" yesterday, but Sam Brown threatened to "knock" him, and he would like to see the "Bongo" man who could "mash" him. (Bongo means an African pure and simple.) "You want, to have the last word do you? well, I am a Jamaica man but your mother was a 'Bongo' and your father a 'John Crow,'"

To return to "Bound Brook" or "Bog," there is a dark side to the life of a "banana planter": up at six in all weathers to meet the stragglers coming from different directions and having an argument about the time of day and doubting their being late to muster by the cow pen gate; some are told off to "billing bush," some to "hoeing grass," some to "heading out bananas," some to "digging" and "heading out suckers" for planting—coolies for "lining" 12 × 12. On arrival of a mail-steamer all these important works are dropped "like a hot potato," and all hands are ordered off to Baker's Wharf, the Atlas boat lets go her anchor, and she is no sooner moored stem and stern to the Atlas Wharf, than we board her amidships with our bananas, "Only six hours to load, boys; 13,000 (thirteen thousand) bunches to go below; hurry up there; 'walk and talk' 'bananas' from the shore!" "Come along my hearties." "So, my loves, step up and see the 'teamer'" (steamer). Sometimes the people would be turned out to load a steamer through a telegram advising her arrival, and the captain would stop outside the harbour until daylight. I have been at the wharf tallying thousands of bunches down hatches, and nigger-driving until 12 o'clock at night on an empty stomach, with a stench strong enough to breed cholera from rotten fruit in and around the wharf. Another time, I turned out to the steamer's whistle, and trudged along the muddy road in the dark, splashed all over with mud, and stepping into crab holes. "Why," I said to myself, "this is worse than coffee planting in Ceylon, or I 'm a Dutchman!" Then next morning a messenger would ride out from the Bay to say that there was not enough fruit to load up a schooner and that we were to cut all the "full" trenches and send them in at once.

Now, "there was no rest for the wicked," I had to turn out again to superintend the cutting or "harvesting" of "full" fruit, and when the people were at the other end of the estate I should be obliged to hand the big bunches into the waggons or detain the carts, consequently my clothes were all stained with the juice of the cut stems. Then again, after the people had finished work and gone home, the carts and waggons still had to remove the balance of the heaps of fruit cut from the different fields; this necessitated my waiting until long after dark to see the last bunch delivered to the cartman. On arrival at my cottage, the mosquitoes and sandflies had taken charge and disputed my entrance; anyhow they exacted black mail to the extent of a considerable quantity of my blood, and set my body itching to such an extent that sleep was impossible. A curtain had been ordered, and the muslin and cloth purchased, but the bedstead was not made by the carpenter Gregory, therefore Alice Doyley could not take the measuremeut for the curtains. In saying that my eyes were scarcely closed during the whole night I would be under the mark, and fever would have been the result had not "forty winks" been snatched during midday after breakfast. It is not fair to your readers to give them only the bright side of the picture. There are very few Europeans in Port Antonio, so I made very few acquaintances.

Most proprietors of Banana Plantations are storekeepers too, and are therefore not dependent on the fruit: hence, when there is a fall in the price, as there often is, after the summer, they are not much affected by it, and sixpence a bunch will pay for cultivation. Meanwhile their stores are keeping the ball rolling, and if a rum license is added to general storekeeping a little fortune is realized, for I have noticed in Jamaica that owners of land property, owners of good stock, owners of household property in the town, and owners of pretty wives, have in many cases dabbled in rum. There are too many rum-shops in Jamaica, and they are beginning to feel the hardness of the times, as, to quote a member of the new Legislative Council, "the rum drinking part of the community" have left Jamaica to cut the Panama Canal.

It is difficult to tell whether there is any smuggling carried on between Jamaica and Cuba: anyhow Spanish gunboats are always in and out of Port Antonia. I often put the question, "What does the Spanish man-of-war want here?" and the reply was generally "Oh, only to watch for people carrying firearms and ammunition to Cuba." The island of Cuba is only ninety miles from the coast of Jamaica, and it would not be any matter of surprise if a

few Havana cigars were smuggled into Jamaica. There is one reason for thinking this, and that is that the Havana cigars are often cheaper than the common Jamaica weeds, and that certainly looks "fishy." On the Isthmus of Panama a bundle of 25 Havanas of the best quality could be bought for half a dollar and sometimes a quarter of a dollar, 1s. whereas no kind of weed could be obtained in any of the hotels under ten cents, or fivepence, each cash.

My domestic arrangements at Port Antonio required occasional reform. When I discovered it was absolutely necessary to have a housekeeper I consulted the manager on the subject, and he recommended Miss Susan Moore of Atlas Town No. 16. I called on the young woman, found her fat and good-looking, bright, laughing eyes, and the finest set of teeth ever seen; she offered me an easy chair and said she was quite "puzzled how to act," the fact of the matter being that the schoolmistress had offered her sufficient needlework to employ all her time. "Really, sir, I am at a total loss to know *which to embrace*" "Well," I said, "it would perhaps be better to *embrace*. me than the old schoolmistress."

The result of the interview was a postponement to duly consider the matter, and Susan Moore to my perfect knowledge did not do a hand stroke of work for three months.

My domestic arrangements in Port Antonio are worthy of a fresh chapter, so we will wind up this letter in the usual way, by saying "to be continued in our next."

H. C.

DELI NEWS.

We learn on good authority that Messrs. Baron de Horn, Wortman, and Sanders intend to start a company with a large capital for working tobacco estates in the district of Tanjong. Great schemes are also in hand for Deli, and rumours are afloat that a new banking institution will be established at Medan its business lying more in financial transactions than in plantation speculations properly so called. The failure of the Netherlands India Mercantile Bank leaves a vacant place among Loan Offices doing business with Deli planters which the promoters of the scheme appear desirous of filling.—*Straits Times.*

PLANTING IN NETHERLANDS INDIA.

(*Translated for the "Straits Times."*)

DEPRESSED PLANTING—VOLCANOES—COOLY RECRUITERS

A report of the Planters' Association meeting recently held at Surakarta, as published in the Samarang *Locomotief*, draws the following discouraging picture of the present state of plantation enterprise in Mid Java.

The hard times spare scarcely any one, and though all the sugar growers may rejoice in an overflowing crop the prices ruling for sugar have fallen so unprecedentedly low that many estates have been worked at heavy losses and are threatened with total ruin, unless a change for the better set in by a rise in the value of sugar within the course of this year. Coffee has been in a still more deplorable condition, from, in consequence of the spreading leaf-disease, the last crop proving shorter than ever before, it amounting on many estates to barely a tenth part of the crop of 1883, prices moreover having for years been disquietingly low. Should the coffee leaf-disease not be checked but go on working havoc, certain ruin is in store for most of the coffee plantations, and it is only by setting about the cultivation of indigo, cacao or other crops, that some estates will be enabled to grow products for the European market. Indigo, at first high in price, has also followed the other export articles in falling in value, and is now so neglected that there is no longer any demand for it so to speak, and hence it has to be shipped of on growers' account. Tobacco, after having been for years a very losing article, has now slightly improved in value. Unfortunately, however, its cultivation has almost been given up in this part of Java. No other kinds of cultivation are now carried on here upon a somewhat large scale by planters, who are now threatened by a fresh calamity in the shape of cattle murrain.

The attention of the authorities concerned is hereby directed to coolie recruiters come over from Singapore to Batavia. These people entice away silly Javanese with fine promises, and whenever promises prove of no avail, with the chink of silver coin, to follow thither. At Singapore they are made over to cocoa, tapioca, coffee, tobacco, and sugar growers, under engagements for 5 and even 10 years. The bounty, amounting in some cases to 50 guilders and upwards for each coolie, is put by the crimps into their own pockets, while they allow Javanese to work hard for from 5 to 10 years on wages too high to die of and too low to live on comfortably.

THE PROPOSED EXTRA TAX ON TEA-GROWERS.

Some weeks ago was published in the *China Mail* a translation of a proposal made by the Board of Revenue to levy a tax on tea at the seat of production. The Court directed that it should be tried and reported on by the authorities in all the provinces. The head lekin office of Hupei has now moved the high officers of that province to represent to the throne that, in the present depressed condition of the trade, such a tax would do far more harm than could be compensated for by the funds so raised for military purposes.

The *Shén Pao* of the 10th of April contains a very sensible leading article on the above protest, which may be briefly summarized as follows:—While admitting the excellent intention of the Board, the writer denies that any real benefit would accrue from the tax. The China tea-market has of late been much depressed—a depression which each year intensifies. Silk and tea used to be the chief exports of China, and their value far exceeded that of imported opium. Now no profit can be got from silk, and tea has decreased in amount by several hundred thousand chests. This is due to the foreign merchants refusing to pay the price demanded. At the beginning of a season telegrams announce that the foreign market must have so much and that prices will be high. At once the teamen hurry to the hills and engage to take so much at a rising price. But before it reaches the port, perhaps, the market is reported to have fallen. The teamen have to sell at a loss to the foreigners, or if they ship on their own account, lose still more heavily. If this extra tax is imposed, the purchases of teamen will be still more checked. What is the good of exasperating the traders and ruining the trade?

It is a clever device to give foreigners no chance of protesting by levying the tax from the growers. But the Board does not see that the present stagnation of trade is caused by the foreign merchants refusing to take delivery of tea, or, because of the adulteration of China teas, or the high price asked for inferior grades, cutting down the price in every way, whereby many teamen have been ruined. This "cutting" is not solely due to their desire to lower the price of China teas but also to the competition of Indian and Japan teas, which diminish the importance of China teas in the market. Meanwhile Chinese dealers, from shortsighted avarice, give additional justification for the complaints of foreigners by adulteration, and the growers have not yet devoted attention to improving the plants and the mode of firing and preparation, but simply try to get an unnaturally high price. We have repeatedly urged those concerned in the trade to endeavour by honest industry

to improve it as the only hope for the future. Unless this be done, we fear that not only will all China's profit from foreign trade be extinguished, but even a direct drain on her resources may ensue. For the question of tea export is of serious consequence to the State. To neglect to improve the preparation and merely levy extra taxes will kill the China tea trade. We hope that all the other provinces will follow the example of Hupei.—*China Mail*, April 3.

SECHUEN OR UNKNOWN INLAND CHINA:

MR. HOSIE'S INTERESTING JOURNEY: NEW VEGETATION AND INDUSTRIES.

An interesting narrative of a journey in a remote inland province of the Chinese Empire has recently been issued in the unattractive form of an English parliamentary paper. It is a report by Mr. Alexander Hosie of a tour through Central Sechuen in the months of June and July last year. Sechuen lies upon the upper waters of the great Chinese river, the Yang-tse-Kiang, which traverses it for eight or nine hundred miles. Mr. Hosie left Chuncking, an important town on the Yang-tse-Kiang, at the beginning of June, and going eighty miles north, reached the important trade centre of Ho Chou. Here three streams, which drain northeastern Sechuen, meet to form the Chiasling River, which flows down to the Yang-tse-Kiang at Chung king The country from which these rivers come is rich in salt, silk, safflower and other products, which are shipped at Ho Chou, and sent down to the Great River. In return for these exports come foreign goods which are distributed from Ho Chou as a great commercial centre. Leaving Ho Chou on a wet Summer day, with bearers and carriers, who like all the Chinese, had great dread of a drenching, Mr. Hosie struck westward for the Min River, intending to visit the famous Mount O'mei, and then to proceed to the highest navigable point in the upper Yang-tse, or, as it is there called, the Chin-sha-Chiang or River of Golden Sand. The road lay through a rich country, full of small farms with homesteads nestling amongst the trees. Bamboo and fir abound, the palm and the banyan are scattered here and there, the wood-oil tree is dotted about on its favorite bits of rocky soil, plantations of mulberry are met with, and thick copses surrounded by walls, mark the residences of landed properties. On terraced hills and in bottom lands, there are fields of paddy fringed with beans; the Indian corn is nearly ripe; tobacco is well advanced; the melon shows its star-shaped flower; and ginger-looking like young bamboos are springing up from carefully prepared beds a foot deep and half a foot broad. In the fields are rustics clad in palm coir cloaks, taking advantage of the rain to plant the sorghum which they have plucked from the nurseries It is a picture of an agricultural country and an industrious and contented people. Stone bridges cross the streams, excellent coal is mined in the hills and sold at the pit's mouth for less than a dollar a ton, and there are other signs of trade. At the large market town of Patang, reached on the evening of the second day, a sort of pleasure fair was going on, and the rustics who had swarmed in from the country were listening to music, if clashings of cymbals, screechings of pipes, and beating of drums, are worthy the name. The crowds were anxious to make a little fun out of the foreigner, but no harm came of it, and quiet was found in the windowless room of a crowded inn.

Thus the journey continued from day to day. The roads were good, but most tortuous, winding round the paddy fields as though the old engineers had no notion that two sides of a triangle were greater than the third. In one town it was market day, and the chief goods for sale were tea and cottons. The tea was sold at 3 cents a pound, and was as good as that which in England is sold at two and a half shillings, or in America at 75 cents. The cotton cloth was of native manufacture. Cotton is largely manufactured in the district of Tatsu, where the price of raw cotton is about a shilling a pound. North of the city of Tatsu lies a range of hills in which iron and coal are found in abundance. There are smelting works in the market town of Yulung-chang, which give work to more than two hundred families. Each of the mines employs about two hundred hands and the daily out put of each mine is about two tons of iron plates. The rivers are everywhere the highways of commerce. In the course of his journey Mr. Hosie visited the sacred mountain O'mei, which has been described by Mr. Baber. Hundreds of pilgrims were going thither on foot, and shrines and temples thickly dotted the road. At each of these the pilgrim makes obeisance, lights a joss stick or a candle and passes on. Beggars swarmed; but the priests begged most persistently.

On the top of the mountain is the temple with a frightful precipice behind it. Here the glory of Buddha is seen when the sun bursts through the clouds over head and reveals his image on the clouds below. A dense fog hung over it when Mr. Hosie was there, and he saw nothing but the impenetrable haze. After leaving O'mei some serious difficulties arose. At one point in the journey Mr. Hosie and his bearers and servants were nearly starved, and at another were in some danger of being captured by the Mantzu, who live in the mountains and sometimes make raids on the villages. Everywhere, too, the curiosity of the country people to see the foreigner was a source of annoyance, though the escort provided by the Chinese authorities prevented any real danger. The inns, with one solitary exception, were execrable beyond the possibility of description. Mr. Hosie expresses his perfect surprise that travellers in the interior of China are not dead in the first week. The return journey was made on the river.

The object of the expedition was to collect information on the subject of the white wax made by certain insects in China, and to procure for Kew Gardens specimens of the trees on which the insects live, and of the wax they produce. This object seems to have been accomplished. The chief wax-producing district in China is that western end of the province of Sechuen which Mr. Hosie traversed, and especially the districts of O'mei, Chien-wi, and Loshan. It is a double product. The wax insects are produced in Chianchan, and carried over the mountains to the wax trees in Chiating, of which O'mei and the other districts named form a part. The insect tree is an evergreen, with dark glossy, pointed leaves, which spring from the branches in pairs. On the bark of its boughs and twigs small excrescences or galls are found in the early Summer, and these galls on being detached are seen to contain swarms of minute insects, and in some cases a small beetle. This beetle eats a hole in the shell and lets the insects escape. The Chinese collect these galls in the early part of May and convey them to the district where another evergreen called the wax tree grows The galls are attached to this tree and the insects creep out and adhere to its branches. They appear to suck the sap and to deposit it in the shape of white wax. In the course of from ninety to a hundred days the branches thus become thickly coated, and in good years the wax thus formed attains the thickness of a quarter of an inch. At the proper time the branches thus coated are lopped and the wax rubbed off by the hand, and heated in water. It rises melted to the surface, is skimmed off and run into moulds, and

thus forms the white wax of commerce. The Chinese mix some of this wax in tallow candles to give them firmer consistency. The candles are dipped in white wax, and thus acquire a sheath which prevents "guttering." An inferior kind of wax is squeezed from the boiled insects themselves, and they are then given to the pigs. Mr. Hosie has succeeded in sending home to Kew Gardens some specimens of the tree on which the insects originally grow, as well as bunches of seeds from the wax tree to which the insects are transferred. He had not with him any microscope powerful enough to enable him to discover how the wax insects feed or in what way they deposit the wax. He found, however, that they construct galleries or passages in the wax deposit itself, which reach from the bark to the outer surface of the wax. He has seen them thickly studded on the bark and apparently motionless.—New York *Hour*, March 21st.

CEYLON UPCOUNTRY PLANTING REPORT.

CEYLON'S NEWEST PRODUCT, COCA: GREAT DEMAND FOR SEED—HOW TO KEEP DOWN THE BEEF-BOOK—A LARGE ORDER.

11th May, 1885.

The seeds of our newest product, coca, are now being distributed from our Royal Botanic Gardens at Peradeniya, at a charge of twenty-five cents for fifty. The applications I hear are very numerous, and although the plant is said to grow best from an elevation of 2,000 feet and upwards, it has every chance I fancy of being tried at almost every altitude. Those who have any experience of this plant tell me that it grows very well among rocks, planted in the crevices, with not too dense a shade; whereas in the open it runs more to seed than leaf. As it is for the value of its leaf that it will be cultivated, this hint may be worth attention.

The power of the coca leaf for arresting hunger must in time, I fancy, make it a favourite vegetable with the economical planter. It will be a final solution to the problem of how to keep down the beef-book. And yet I don't know. The late hard times have developed in many an ability for being able to "knock along" on so little that to reduce further would certainly mean collapse. I once heard a planter give a bazaar order for half-a-pound of beefsteak and a box of matches, at the same time handing twelve-and-a-half cents to his servant so as to have all the advantages of a cash transaction! It would be very unsafe I think for a man of that kind to have coca to browse on, besides running the risk of spoiling what appeared to me then, and appears to me still, a noble specimen of the art of economical living. PEPPERCORN.

CARE IN SELECTING SEED.

In the *T. A.* of January last, on page 509, there is a letter signed "S." on the subject of the want of care in selecting tea seed, in which the writer reminds planters that other seeds require care in selection, as well as tea. The remarks made in that letter are all undoubtedly true, and every planter ought to know that such is the case by this time; but planters have a habit of allowing the dead past to bury its dead, and, although they probably all are quite willing to admit that the choice of immature and unhealthy seed was as much to blame as anything else, in the bringing of leaf-disease on coffee, and in damping off in cinchona beds, still we find them rather backward in taking the lesson to heart in the matter of tea seed. About the year 1870, there was such a bustle to get coffee estates planted up, that any sort of plants were made use of: from weedy estates, native gardens and out of the jungle, plants that having been half-choked had grown long, spindly and unhealthy. Naturally they fell an easy prey to leaf-disease, and once that pest was well established, the older and stronger coffee trees became infected, and now the poor old "King" may be said to be *in articulo mortis*. Then came the rush for cinchona and any sort of seed was bought up. I remember a neighbour of mine who had some trees about four feet high, which suddenly began to get sick; then seed in great quantities appeared on them (Nature making an effort to reproduce herself) and he carefully had each of the bunches of seed put in a gauze bag and thus secured the seed as it fell. The trees ultimately died, and the seed was sown by him in his nurseries, and in course of time it came up and proceeded to damp off. Everything was blamed by him except the right thing, viz., that the seed was grown on unhealthy and immature trees. So far Ceylon planters have been very fortunate with tea: they bought, in many cases, tea seed which no Assam planter would have used, but their splendid climate has pulled them through and the bushes have more than astonished them. But I have never yet seen any comparison made of the yield from tea bushes raised from the best seed, at say R150, and that from seed which cost only R30 a maund. If inferior seed can grow into such bushes as are to be found in Ceylon, surely the bushes grown from the best seed, had it been planted in the same place, would have done better.

In farming at home, one learns the same lesson with regard to the seed used: to plant potatoes which were taken from the roots of unhealthy plants or from plants that have been pulled up as soon as the potato disease began to show itself, and which of course were hardly ripe, would scarcely be a judicious thing to do, and my own impression is that finger-and-toe disease amongst turnips arises as much from growing these vegetables from seed taken from an unhealthy plant, instead of getting fresh seed from some one who has not been troubled with the disease. I have known farmers who, have built their corn into stacks before it was quite dry, these gradually got heated and the grain became discolored. This of course, reduces its value in the eyes of the grain merchant, and, rather than sell at a lower rate than the price current, the farmer sows it as seed next year, holding the idea that anything is good enough for seed. Need I say that the germinating power is partially gone and the crop therefrom is, in consequence, not at all a good one. My grieve, who has grown up boy and man on the farm, tells me that it is all very well to say that a change of seed is a good thing, but the best crops that have ever been grown on the place have been from our own grown corn. This I can easily account for. He is a most careful man (the pity is that there are so few like him), who never reaps till the grain is ripe and never leads till the sheaves are dry, and consequently the grain is certain to be good seed. But I have seen stacks steaming with heat, having been built when the sheaves were only partially dry, and these, when pulled down, have had more the appearance of manure than unthrashed straw. Can you wonder that the grain from this should turn out indifferent seed? Now, if seed taken from unhealthy turnips or grain taken from corn, which has been cut when not quite ripe, result so unfavourably at home, why should not the same thing obtain in the matter of tea and cinchona seed in Ceylon? I think that this is a subject to which sufficient attention is not paid, and I have not the least doubt that the quality of the seed has much more to do with the return of

grain than we have any idea of, and it is quite possible that the same may be found to be the case with regard to tea, and that the seed which cost most at the beginning will bring in the greatest number of rupees in the long run. COSMOPOLITE.

TEA AND COFFEE IN CEYLON.

LINDULA, May 12th.

There are already extensive clearings for and plantings of tea in the Great Western Valley, and the process of superseding the old product by the new is certain to go on now at an accelerated pace. I see a correspondent of the *Observer* complains of the tone of contempt which some have adopted in speaking of coffee. I do not know that I have laid myself open personally to this charge, any more than I can be included in the category of irreverent persons who, according to Sidney Smith, were capable of "speaking disrespectfully of the equator." Regret at the decadence of the monarch who once reigned with undisputed sway has surely been the prevalent one,—regret and grief. But the truth must be spoken: coffee, except in special districts and on exceptional estates, has either ceased to promise fruit by making "a good show" with blossom, or, having made such show, has failed to justify promise by performance. Were this the fault of the tree, there would be some justification for a tone of contempt. But coffee is not itself in fault: only unfortunate in being the victim of fungus, grub, bug, and unfavourable meteorological conditions, under which the candle of its life has been burnt at both ends and fatal debility produced. In the young districts served by the railway now completed, the signs of sickness even unto death may not be so apparent as in the old, where over wide areas, as Mr. Joseph Fraser truly told you, the bushes bear no berries at all. But, even on many young places, where the blossom gave splendid promise of fruit, the resultant crop will not pay the cost of cultivation, harvesting and preparing. Under such circumstances you must not wonder that so many have finally given up faith in coffee and cut it down or rooted it out to make room for tea, which as yet seems proof against insect and fungus blights and the crops from which, being leaves, are not liable to be destroyed by such rainfall or even rainstorms as occur in Ceylon. And this raises another interesting question: that of the revival and possible extension of the practice of keeping cattle on estates solely or chiefly for purposes of manuring. The custom ceased to pay in the case of coffee, for many reasons: cattle-manure actually bred the destructive white grubs, while crop after crop of leaves which the manure enabled the trees to produce merely became fresh food for the fatal fungus; and, even where crop formed in good plenty on the trees, it was liable to be dashed off by unseasonable rains. Tea, which responds in the most satisfactory manner to applications of ammoniacal manure, is not liable, or but little and rarely liable, to such contingencies, and were there only better markets in Ceylon for milk, butter and fat meat, I should entertain no doubt of cattle establishments paying well on tea estates. Even on many coffee estates they paid before the advent of leaf-disease, root grubs, scale insects and unfavourable seasons; and a neighbour who has kept up a stock of cattle obtained originally for coffee, told me recently that he was going to make considerable additions, assured as he was that keeping cattle for the manuring of tea would pay. It seems desirable that this question should be carefully considered and fully discussed. Of the liberal response which tea will make to manuring or even what the Indian planters call "cultivation," that is stirring the soil, there can be no question. That coffee has ceased profitably to respond to the highest possible cultivation, I had proof in a visit to the celebrated Kandanuwara estate near Matale. Here every bush had a little manure heap of its own, all weeds, leaves, &c., being swept round the roots. One effect of leaf-fungus in many places has been so to enfeeble coffee bushes as to prevent their being able to throw out feeding rootlets, even where grub did not prey on such rootlets. But Mr. Hugh Fraser bared for my inspection masses of rootlets which looked as flourishing as the ample and fresh-looking crop of leaves. But even on this estate, until not long ago so famous for its large and profitable coffee crops, the old favourite is giving place to the new, while not far asunder from Kandanuwara is Damboolagalla, including the ancient Pittakande, whence the late Mr. Young had long derived an income of £6 000 to £10,000 per annum. Here also, Mr. Young, before his lamented death, having issued the fiat, the coffee bushes, which in their day gave such truly splendid returns, have given or are giving place to tea. So almost everywhere.

I have thus anticipated portions of my interrupted notes of a journey to see the tea grow, and, as tea now, and not coffee, is the main justification for that railway which the *Observer* did so much to urge forward, and which its conductors hope to see in course of completion from Nanuoya to Uva before this year is out, I may be allowed to say a few words about topics noticed by Col. Money and Mr. Jackson: the distance apart at which tea bushes should most advantageously be planted, and the period during which flush-yielding plants can be safely plucked between prunings. The writer returned from a visit to Darjiling in 1876 strongly impressed in favour of such close planting as 3×3 feet at high altitudes in Ceylon. But experience of growth and the necessities of cultivation at between 5,000 and 6,000 feet has compelled us to favour $3\frac{1}{2} \times 4$ feet even at this elevation. We need, therefore scarcely say that we should not advise any closer planting in the lower and hotter and more forcing portions of Ceylon. No doubt a closely-planted tea field at two years old completely covering the ground with luxuriant growth is a beautiful sight, and the plausible reasons for such close planting as even $2\frac{1}{2} \times 3$ feet are quick returns for expenditure and the rapid protection of the soil from combustion by a tropic sun. As has been pointed out, heavy returns at an early period of the existence of an estate are sure to result in earlier exhaustion, and such saving of humus as is secured by completely covering the soil is scarcely a gain when placed against the difficulty, the almost impossibility, of cultivating and aerating the soil. Where I would advocate such close planting as even 2×2 feet is on *very* precipitous steeps: on such places the soil needs to be bound, and there is no better permanent binding plant than tea, sending out, as it does, lateral roots from which fresh plants spring up, if encouraged, as they ought to be on such places. As to Mr. Jackson's general objection to planting steep land with tea, one answer is that most of the available land in Ceylon is more or less steep-featured. The compensating advantage is better drainage than can be secured on flat and swampy land such as is so frequently cultivated in Assam, elephants being needed to wade through floods in the rainy season. Then, as Mr. Owen pointed out, our soil, while of good quality, especially for tea, is far more tenacious and can hold its own against rain and wash so much better than the rich but very friable alluvial deposits on the banks

of the Brahmaputra. Many coffee planters were wont to affirm that they obtained their best crops on the steepest land, and experience in a good many cases seems to prove that the process will be repeated in the case of tea. Abbotsford is certainly steep-featured as well as high in altitude (4,600 to 6,000), and yet tea grows here with wonderful luxuriance. High altitude is no doubt compensated for by nearness to the equator (7° instead of the 27° and over of Assam), while Ceylon is an island instead of part of a great continent at the foot of the loftiest mountain chain on the globe.

But to return from the Himalayan snows to the genial climate of our own mountains and the mountain railway with which I began. The railway to Nanuoya is practically complete, and we trust it will not be long at work, when Uva will be at length assured of long-denied justice, by the cutting of the first sod of the section to Haputale.

We have had heavy rain from about 10-30 a.m. to 1 o'clock, the result of a thunderstorm which seemed to approach from the north-east. Rain has commenced heavily again at 2 30 p.m.

I had almost forgotten the question of plucking without pruning. When trees become "scraggy," it is evident they need pruning. Our experience here is that tea bushes can be plucked for two years consecutively, but a period of 18 months is probably the safe limit.

MR. D. MORRIS'S REPORT ON THE JAMAICA GARDENS.

We have received Mr. Morris's Annual Report on the Public Gardens and Plantations of Jamaica, which, as usual, contains various matters of much general and local interest. We have already referred, in noticing a similar report from Queensland, to the immense economical importance of such institutions as this, and we are glad to perceive that such competent authorities as the late Royal Commissioners in the West Indies and Sir Joseph Hooker, have publicly recognized the value of Mr. Morris's labours. The former suggest that in all the lesser islands "plant committees" of the residents should at once be formed to correspond with the establishment in Jamaica, while Sir Joseph Hooker, in commenting on this recommendation in his letter to the Colonial Office, stated that there can be no doubt that the future prosperity of the West Indies will be largely affected by the extension to other islands unprovided with any kind of botanical establishment of the kind of the operations so successfully carried out by Mr. Morris in Jamaica. But he thinks that mere committees will not be enough: botanical stations on a cheap basis are an essential condition for doing anything in an effective way. The money value of rain in Jamaica is well shown in a paragraph in the report quoted from Mr. Maxwell Hall's estimate. A comparison has been made between so many inches of rain per annum and so many casks of sugar per acre. Thus there were 1,559 casks per acre for 79 inches rainfall and 1,441 casks with 56 inches, so that the difference due to a larger or small island rainfall is on an average nearly one-tenth of the export sugar crop. This one-tenth export crop, for sugar and rum, represents in value nearly 100,000*l*. But if other produce, which is likewise affected by a greater or less rainfall, such as coffee and pimento, the difference would amount to a very considerable sum. During the year considerable attention was devoted in the herbarium to the medicinal plants of the island, and to forming not only a collection of botanical specimens, but also of the barks, roots, and the portions used for medicine. The value of his herbarium to the commercial interests of the West Indies was shown while working up the botanical classification of the indigenous plants capable of yielding fibre. It was found that the common native *Agave* (aloe) of Jamaica was not, as had been represented in books on Jamaica plants, the *Agave americana*, but an entirely different species, the *Agave keratto* of Salmdyck. The application of this difference, which appears to him only one of botanical nomenclature, to the industrial arts is that, under the belief that this plant was *Agave americana*, and therefore capable of yielding valuable fibre, large sums of money were spent and lost in getting out machinery to clean fibre which was of inferior quality.

At the end of the report on the Jamaica public gardens above referred to, Mr. Morris mentions some curious instances of superstitions among the negroes with regard to plants. The plantation labourers believe that if they take up the horse-plantain suckers (*i.e.* those with long fingers), and then take up one of the maiden plantains (with the short fingers) while the gum or juice is still fresh upon their cutlasses, and they use the same cutlass, the maiden plantains will produce horse-plantains, and this was said by them to be a matter of common experience. It is believed also to be unlucky to point the finger when speaking of any growing plant in a provision ground, or even to name a plant which has recently been planted. It is stated even by intelligent Europeans that if the seed of the shaddock (*Citrus decumana*) is planted, there is but one in a whole shaddock that will produce good and pleasant fruit, and also that there are fifty-two seeds in a shaddock, only two of which produce the real shaddock, while the others produce a variety of fruits such as the sweet lime, forbidden fruit, grape fruit, chester fruit, and orange!—*Nature.*

THE VANILLA PLANT has been found growing on the borders of the everglades of Florida.—*American Grocer.*

TREE-PLANTING IN BENGAL.—In the Santal Parganas during the year 1883-84 tree-planting along the roads was very carefully attended to. The trees were maintained with good care, and are all thriving luxuriantly. About 5,000 young fruit trees, chiefly mangoes, were planted along the road-sides.—*Pioneer.*

THE PLANTERS of the province of Bahia seem willing to take immigrants on the *metarie* basis. They, by the Imperial Bahia Institute of Agriculture, propose two-thirds for the planter and one-third for the laborer, or even half for each, if the capital invested in land, machines and live stock be taken into account. The planters will furnish the necessary for the immigrants' first establishment.—*Rio News.*

TEA MACHINES: THE CRY IS STILL THEY COME.—A planter writes:—"Enclosed I send you a circular of a Tea Sifter I am trying to introduce into Ceylon, and hope to be able to send you particulars of a new Drier shortly" The Sifter is "Baillie and Thomson's Patent" which is highly spoken of.—We also hear of another Tea Drier on a new principle being perfected in Colombo, so there will be no lack of competition.

MOVEMENT OF GROUND NUTS AT PONDICHERRY.—The French steamer "Province," 3,872 tons register, Captain Vert, belonging to the Compagnie Nationale, left Pondicherry for Marseilles on the 15th instant, having taken in about 35,000 bags of ground nuts The "Provence" was advertized to leave on 18th, but having completed her loading earlier than was expected she got away on Wednesday evening. The French steamer "Suez," 1,064 tons register, Captain Morgan, leaves on Monday, 20th, for Marseilles, with 30,000 bags. The stocks are still very heavy, as freights cannot be obtained. Prices have gone down to R9 per candy nominal.—*Madras Mail.*

TEA AND OTHER PRODUCTS IN SOUTHERN INDIA.—We call attention to the letter in our Supplement addressed by Mr. W. J. Kemp to *The Field*, in which a very favourable case for the extension of tea cultivation in Southern India is made out. Mr. Kemp goes so far as to show profits rising from 11½ to 55 per cent on capital invested. Who would not rush into tea after this; but many of his readers will think it strange that so few India tea concerns pay even a steady 5 to 6 per cent. Mr. Kemp is absurdly out in talking further on of ceara rubber yielding 300 lb. per acre value £45 (profit £37!) after the 6th year. Such statements only do harm to the cause of planting and new products in the East. The correspondence which has led to this letter will be given in full in our *Tropical Agriculturist.*

Correspondence.

To the Editor of the "Ceylon Observer."

HARVESTING CINCHONA BARK.

Deltota, May 12th, 1885.

DEAR SIR,—Can you kindly let me know what amount of bark (shavings) a cooly is expected to bring in a day. The trees on this place are from two to five years old and are fairly healthy. My coolies who were new to the work began about a fortnight ago by bringing in an average of 57 lb., and today they brought in an average of 130½ lb. green bark. Is the latter a fair amount? My average from the time I commenced barking is about 110 lb. The bark loses about 67 per cent of its weight, so that a cooly brings in about 36½ lb. dry bark. Is it necessary to thatch the trees after shaving? I find it costs a great deal, about 5 men in all for one man shaving, *i. e.* cost of cutting mana and carrying thatching, cost of drying &c.

An early answer in your valuable paper will greatly oblige, yours faithfully, B. E.

[We quote from Owen's "Cinchona Manual"—a copy of which "B. E." should have by him—as follows :—

The amount of bark that a cooly can take off depends greatly on the weather, the size of the trees, and their health. With large trees, in wet weather, a big task can be done; if the bark is unhealthy, it adheres to the stem, and is very difficult to separate. The following will give an idea of the cost of this work for five year old trees. For *Succirubra*, quill 25 to 35 lb per man (large and small together), of green bark; branch from 40 to 45 lb; twigs, from 22 to 25 lb; root, about 20 lb. If the stems are whittled a large quantity can be taken, 50 to 60 lb, and sometimes over. For *Officinalis*, quill 15 lb; branch 35 lb; twigs 13 lb; and root 18 lb; are average rates.

Of the cost of *mossing and renewing* processes in Ceylon not much is known. *Officinalis* appears to cost about 20c. per lb harvested by this process; this is when moss is plentiful in the surrounding jungles, a woman bringing in 40 lb as a day's task; but when moss is not obtainable, grass may be employed, and reduces the expense greatly. A gentleman in Maskeliya gives the cost of mossing and renewing *Succirubra* at 12c. per lb dry, and this proportion is about fair to the rate for officinalis I have quoted. At high elevations, covering the shaven or stripped trees is not now in many cases, considered necessary. Let "B. E." try both plans and report result. —ED.]

SORTING AND THE FINAL PACKAGE OF TEA IN COLOMBO.

12th May, 1885.

DEAR SIR,—"S." (page 297) is nothing if he is not emphatic; so long, however, as our supplies of cinchona continue to come forward on the present scale, we must not be too precipitate in turning our stores into baths and ballrooms whatever we may do with our barbacues. When "S." wrote his letter of 8th, he possibly had not seen my reply to "T. P.," or he would have noted that even before I saw Mr. Scovell's figures for sorting I had coupled with the idea of using bags the suggestion, that sorting should continue to be done on the estate. In this case the objection that inferior tea would get mixed through breakage on the way with the finer teas falls to the ground; and it only remains to consider whether an efficient package of this description can be secured—and at what price. The slight breakage that sorted tea might be subjected to in these packages would be of small account. The wear and tear of waterproof bags might be minimized by enclosing them in an ordinary gunny. Messrs. Davies & Co.'s waterproof bags are lined with stout canvas, so that no inner bag would be necessary. The weight of the double bag would be under 5 lb, and they would hold on an average 1 cwt. of tea. I have just tried one with some broken souchong, and find it will contain 110 lb. of this quality. Here then is a package which, whilst weighing little more than 1-6th of a lead-lined chest will bring down 25 per cent more weight of tea. This is equivalent to a saving of 86½ per cent on freight due to package. On tea down as at present the proportion of freight due to package is 25 per cent of the whole—or ¼ per cent per lb. when the total freight amounts to 2 cents per lb. or 50 cents in 100 lb. The same amount of freight is due for packages up, so that for every 100 lb. of tea in which the gross freight to Colombo amounts to R2 and for which chests and lead &c. are supplied from Colombo, R1 has to be paid for freight on the packages up and down. If bags could be used, the freight on package would be reduced to 13½ cents for every 100 lb. of tea, thus showing a saving of 00·865 cents per lb. or R865 on a crop of 100,000 lb. Speculations such as these may be wild or not; but it cannot but conduce to the benefit of the tea planter that they should be thoroughly sifted, even though in the process they should be blown to the winds. I am bound to add that I think the first cost of the bags to which I have called attention is at present prohibitive.

I note what "S." says as to the disadvantage of divided responsibility, and I admit the force of it; but loss by reweighing and final tiring would be no greater in Colombo than on the estate. There need be no bursting of bags en route, nor any pilfering of the contents in my assumed "model bag of the future"; consequently no mixing or damage by rain. And as regards the wear of the waterproofing, are we not growing our own indiarubbers? Why, my dear sir, just look at the vista that this thought alone opens up!—Yours faithfully, C. W. H.

PRACTICAL HINTS ON THE TREATMENT OF THE TEA BUSH BY AN OLD HAND.

9th May 1885.

SIR,—Mr. A. E. Wright in your issue of 5th inst. invites discussion as to whether keeping the stem of the tea bush clean six inches from the ground by clearing off suckers and side-shoots or leaving these to grow is the better mode of cultivation, his own leanings being in favour of the latter. The more experience, Mr. Wright acquires in tea culture, the more, I think, is his opinion to be strengthened in that respect. A clean single stem cannot well be got without allowing the plant to run up a leader to an objectionable height before cutting down: this delays the growth of the side-shoots, consequently they are weaker than the inner ones. Breadth cannot be got without raising the bush to an objectionable height. The central shoots being stronger, the flushes will be long-jointed, and a day or two ahead of the outsides at every round of picking, and the bush making every effort to become a tree. Every tea planter aims at getting the outsides of his bushes to grow as strong and vigorous as the inside. To ensure this he should cut down his young plants at an early stage and get as many of the side-shoots from the collar of the roots as possible—and if they strike out additional roots for themselves (which they will do if close to the ground) so much the better. He will find that his flushing surface and his flushes will be out of all comparison more equal than by the one clean stem principle. A tea bush should be a cluster of shoots, and not a stem with branches. The forming of young tea plants should be gone about at a much earlier stage than is often the case. The young fields should be gone over with the knife, about, say, nine to eleven months after planting, and

all single stems cut down to about six to eight inches from the ground. Experience will prove this to be advantageous and economical. If Mr. Wright would wish to see the full force of the system advocated above, let him select a plant with a number of side-shoots, dig the ground round the plant, cut the shoots half through at twelve or fifteen inches, plant and fix them down with a hooked peg, with their heads turned up of course; these will quickly root and form a circle of plants round the parent one. Mr. Wright could go on repeating till he made his plants broader than the diameter of his water-wheel. He must, however, if he has any awkward questions to ask, such as how he should pluck the centre or manure the plant, &c., apply to "ED. T. A." and not to, yours,

ARBORICULTURIST.

BIRDS' NESTS FOR THE CHINESE.—During the second half of last year several communications appeared in *Nature* relating to the nests from which the Chinese birds'-nest soup is made. Mr. Pryer, whose account of his visits to the Gomantin Caves in North Borneo, where the nests are chiefly found, initiated the discussion, has now addressed a long communication on the subject to an English journal published in Japan, the main points of which appear to be as follows:—(1) Owing to a misapprehension, Mr. Pryer was represented as saying that the bats which inhabit the caves constructed the nests as well as the swifts. The bats have nothing to do with the nests. (2) Mr. Layard, in his letter published in *Nature* (November 27th, 1884), speaks of "traces of blood, from the efforts of the birds to produce the saliva." Mr. Pryer thinks that the patches of brown-red on the nests may be due to blood from the hands of the gatherers, or to the betel-juice which they constantly expectorate, but not to the bird's blood. (3) The birds do not eat algæ; they are purely insectivorous. (4) Mr. Green says (*Nature*, December 11th) that a chemical and microscopical examination of the nests suggests that they are made from the saliva of the bird. This Mr. Pryer regards as a physical impossibility, for the bird could not secrete in a few days a mass of saliva more than equal, when dried, to the entire bulk of its own body, and then do this nine consecutive times a year. He thinks that, undoubtedly, some saliva is used by the birds, the algæ (which Mr. Pryer incorrectly called "fungoid growth" in his first account) being used in the same way as a Japanese swallow (*Cecropis japonica*) uses mud. This bird gathers pellets of mud and works them up in its mouth, forming a strong cement, constructing a large bottle-shaped nest, sometimes nearly two feet long; and exactly as the *Cecropis japonica* uses mud, so the Bornean *Collocalia fuciphaga* uses algæ, producing thereby the delicate structure known as edible bird's nest. Besides, Mr. Pryer states that the nest examined by Mr. Green was probably not genuine, as the substance is very easily imitated, and the high price would stimulate adulteration. (5) His previous theory that the distinction between white and black nests is due to the brown outside of the algæ being used for the latter, he now renounces. The birds can only use the inside, and black nests are simply white nests grown old and repaired frequently. The difference is not due to any difference in the sits or in the kind of bird. This is the writer's present theory. Owing to some accident (a native printer's mishap possibly), portions of Mr. Pryer's paper are not quite coherent and connected, and some of the words and phrases are misplaced with that ingenious absurdity so characteristic of printers' blunders; but we believe we have given the substance of the communication here.—*Nature*, April 16th.

RAIN WANTED.—Rain, we hear, is much needed both at Coonoor and Kotagiri. The coffee blossom which shot out freely a short time ago, are all being scorched for want of a few showers of timely rain. Tens and tons of coffee are thereby being lost. A bad look out for planting interests this season.—*South of India Observer*.

COMMUNICATION BETWEEN CALCUTTA AND ASSAM AND CACHAR.—Gradually the disabilities under which the great tea districts of India laboured in regard to communications are being remedied. Darjiling has now its railway, and at the meeting of the Indian Tea Association, the following remarks regarding Assam and Cachar were made:—Mr. D. Cruickshank said:—I have read with much interest the address which the Chairman has submitted to the meeting, copies of which were previously circulated amongst members, and I am sure you will all agree with me that we are greatly indebted to Mr. Wilson for his full report regarding the various matters which have engaged the attention of the Committee during the past year. Our thanks are also due to the Chairman and other members of the Committee for the time and attention which they have devoted to the work of the Association. We know how fully occupied business men in Calcutta are, and the difficulty there is in finding time for the duties required of those who act on the Committee, and we must all feel grateful to those gentlemen who have ungrudgingly given their services in connexion with the work of the Association. There are several matters referred to in the Chairman's address of great interest to those connected with tea, and regarding one or two of these I wish to make a few remarks. The first matter to which I shall refer is the state of our communications with the District of Cachar. While in the case of Assam the journey from Calcutta to Dibrughar, which a few years ago occupied a fortnight or longer, has now been reduced to five days, Cachar remains, in regard to the length of time which it takes to reach that district, as distant from us as it was twenty years ago. The Chairman has alluded to the proposal for constructing a railway from Chandpur on the river Megna to Dibrughar, passing through Commillah, Sylhet, and Cachar, and then across the North Cachar Hills into the Assam Valley, but I fear it may be a good many years before this work is undertaken, and meantime it is very necessary that something should be done to improve the existing means of communication. The General Committee have addressed the Chief Commissioner of Assam regarding the state of the river beyond Fenchuganj, with the view of steps being taken to improve the navigation so as to admit of small steamers running up to Silchar during the cold season. Failing this, and it is somewhat doubtful whether the impediments which exist can be removed, so as to allow steamers and laden boats to run freely on the portion of the river in question. I think the Committee might consider whether it would not be advisable to try and induce Government to lay down a light line of railway from Fenchuganj to Silchar. The distance between the two places is, I believe, only about 70 miles, and for a great portion of the way a good road already exists, which could be utilized. The cost of the line, therefore, should not be heavy, and it would hereafter form part of the larger scheme for a railway from Chandpur to Dibrughar if the latter should be carried out. Light railways have already been introduced in Assam, and are found most useful. By making a line from Fenchuganj to Silchar and establishing a service of dispatch boats from Goalunde to run in connexion therewith, Cachar may be brought within four days of Calcutta, instead of the journey occupying a fortnight or longer as at present.—*Indian Tea Gazette*.

TEA PREPARING: JACKSON'S VICTORIA DRIER.

GAMPOLA, May 16.

Large parties are flocking daily to Carolina to see the working of Jackson's new drier, the general opinion being decidedly favourable. I was present yesterday, and was much interested and pleased. The capacity of the machine when fully worked is 170 lb. per hour against the No. 3 Sirocco's 70 lb. maximum, the excess in ten hours being 1,000 lb. The quality of the tea is equal, and some think Jackson's superior. The principle of Jackson's machine is greatly superior to that of Kinmond's: in the latter the heated air repeatedly traverses the tea after it is saturated with moisture, but Jackson's carries it off, the moisture in the hot air sinking, in its ascent through perforated webs to its expulsion at the top, from 280 to 118 degrees. Tea is delivered quite dry. Mr. Jackson claims that two men are sufficient, one feeding and one receiving, but say a stoker is added, this is a great saving of labour, and there is no handling from the feeding till the operation is finished. The heated air is obtained from 23 cast-iron pipes four feet above the furnace. The appliance prevents small tea being drawn up by the fan draught. The total weight of metal in the machine is thirteen tons, but three men can carry the largest piece. The fuel has not yet been determined: Mr. Jackson hopes that one-and-a-half to one, while Mr. Megginson considers that one of Jackson's and one No. 1 Sirocco should dry the outturn of two Excelsiors. One Excelsior rolls 400 lb. in three-quarters of an hour. I was much surprised to hear Mr. Jackson and others state that the leaf is so tender in Assam that twice that quantity is rolled. The leaf is sometimes rolled for only ten minutes. The reason alleged is the superiority of jât. The indigenous tea on Kadawella at 2,300 feet elevation is magnificent, yielding largely in excess of the hybrid. The indigenous at 5,000 feet and over is not a success. The turbine here, of forty-horse power, applying only twelve worked simultaneously two Excelsiors, one Challenge, Jackson's and Kinmond's Driers, and a Pulper-sieve. Mr. Megginson takes out the leaf from the roller at the half-hour, sifts out the small leaf in the Pulper-sieve No. 3 mesh, and dries the small tea when fermented on the Sirocco again, rolls the large tea fifteen minutes and dries in Jackson's Drier. The new drying-house is being erected on Carolina. Last week 8,000 lb. of tea were made by Mr. Megginson, and there is the prospect of a rapid increase.

CEYLON AND JAVA TEA.

Ceylon tea planters, when discussing the position and prospects of their industry, usually take into account as competitors in production only the Indian growers leaving out of sight altogether those of Java. It must not be forgotten however that Java has a considerable start of Ceylon in this matter, so far at least as quantity is concerned. Thus, in 1881 the imports of Java tea into this country had already reached 1,216,000 lb., and in 1884 this is increased to 3,586,000 lb. It is true that, in the matter of quality, Java is still very much behind both Ceylon and India. But a Mincing Lane broker who is well acquainted with the trade says that Java teas are steadily rising in favour with dealers and consumers here, and that the low range of prices current has not been peculiar to them, other kinds having suffered in an even greater degree; moreover that those gardens in Java, as well as in Ceylon and India, have suffered least from the depreciation which have sent home the best liquoring teas. It is no doubt a fact that "more attention is now being paid by buyers to the quality of the liquor than has ever before been the case, while teas for mere appearance, that is with handsome leaf and poor cup, are every year being looked upon with loss favour. Many of the best gardens in Java have recognized this fact, we are told, and turned their attention to producing teas with fine flavour and useful strength, in which endeavour they have met with considerable success. Such invoices always command the attention of the trade, and meet with the best reception, averaging naturally the highest prices. There are still many difficulties to be overcome before a perfect tea can be obtained, and a more intimate knowledge of its chemical properties is much to be desired. Machinery has proved a great boon to the planter, but care and intelligence are required in its application, and many a tea has been spoiled through insufficient knowledge of the actual object which it is desired to obtain." There is a great deal of truth in all this no doubt, but it is only necessary to glance at the quotations to see, that, if many of the best gardens in Java have recognized the desirability of producing good liquoring teas for this market, there is still some essential element wanting to accomplish their aim, though whether it be a want of knowledge of the chemistry of tea or natural unsuitablity of the soil I cannot pretend to decide. Here, however, are two paragraphs appearing side by side in Wednesday's *Public Ledger* which sufficiently indicate the relative values in this market of Ceylon and Java teas:—

"JAVA.—In auction 543 chests sold as follows:—Broken tea 7½d to 8½d, Congou 7d to 7½d, Souchong 8½d to 8¾d, Pekoe Souchong 9d, Broken Pekoe 10d to 11d, Pekoe 11d to 11½d, fine 1s 5d to 1s 7½d.

"CEYLON.—The good supply of 801 chests and half-chests 27 boxes, chiefly in small lots, was all sold, prices being rather irregular, excepting for fine which sold at fully the recent advance: Broken mixed 9d to 1s ¾d, Souchong 10d to 10¾d, Pekoe Souchong 10½d to 1s 0½d, fine 1s 3½d, Pekoe fair to good 1s 1d to 1s 4¾d, fine to finest 1s 5¾d to 2s 3½d, Broken Pekoe fair to good 1s 2½d to 1s 8½d, fine 1s 11½d to 2s 5½d, Orange Pekoe 1s 7½d to 1s 9d."

The above represents the bulk of the Ceylon tea sold this week, the total only having been about 880 packages. They met throughout with brisk competition and sold as you will see at firm rates. Loolcondura brought top prices, 2s 5½d and 2s 3½d, its average being 2s4d.—*Our London Cor.*

THE PEARL FISHERIES OF TAHITI.

A recent issue of the *Journal Officiel* contains a lengthy report by M. Bouchon-Braudely, Secretary of the College of France, who was sent by the Ministry of Marine and the Colonies on a mission to Tahiti to study questions relating to oyster-culture there. The principal product of what M. Brandely, with "the summer isles of Eden" fresh in his mind, calls "*notre belle et si poétique colonie de Taïti*," is mother-of-pearl. All its trade is due solely to this article, which for a century has regularly attracted vessels to the islands which compose the archipelagoes of Tuamotu, Gambier, and Tubuai. The mother-of-pearl which is employed in industry, and especially in French industry, is furnished by various kinds of shells, the most estimated, variegated, and beautiful of which are those of the pearl oyster. There are two kinds of pearl oysters—one, known under the name of pintadine (*Meleagrina margaritifera*), is found in China, India, the Red Sea, the Comoro islands, North-Eastern Australia, the Gulf of Mexico, and especially in the Tuamotu and Gambier archipelagoes; the other, more commonly called the pearl oyster (*Meleagrina radiata*), comes from India, the China seas, the Antilles, the Red Sea, and Northern Australia. The shell of the former is harder more tinted, more transparent, and reaches greater dimensions than the latter. Some have been found which have

measured thirty centimetres in diameter and weighed more than ten kilogrammes, while the *Meleagrina radiata* rarely exceeds ten centimetres at the most, and never weighs as much as 150 grammes. Both varieties supply pearls, those of one kind being at one time more favoured, at another time those of the other. This depends on fashion; but, on the whole, those found in the great pintadine are more beautiful, and the colour more transparent, than those of its congener. The amount of the trade from Tahiti in pearls cannot be stated with accuracy, as there is much clandestine traffic, but M. Brandely puts it down approximately at 300,000 francs, England, Germany, and the United States being the chief markets for the fine pearls. The great pintadine is found in great abundance in the Tuamotu and Gambier islands. The situation there is very favourable to them; in the clear and limpid waters of the lagoons they have full freedom for development, and are undisturbed by storms. Mother-of-pearl is found in almost every one of the eighty islands which form the archipelagoes Tuamotu and Gambier. These belong to France, having been annexed at the same time as Tahiti and Moorea, and have a population of about 5 000 people, all belonging to the Maori race. M. Brandely gives an interesting description of these little-known islands and people. The latter appear to hover always on the brink of starvation, as the islands, which are composed mainly of coral-sand, produce hardly anything of a vegetable nature. While the neighbouring Society islanders have everything without labour and in abundance, the unfortunate inhabitant of Tuamotu is forced to support existence with cocoanuts, almost the only fruit-trees which will grow on the sandy beach, with fish and shell-fish which are poisonous for several months of the year, and often they have to kill their dogs for want of other animal food. There are no birds, except the usual sea birds; no quadrupeds, except those brought by man; no food resources necessary to European life, except what is brought by ships. Although the people are gentle and hospitable, they practise cannibalism, and M. Brandely suggests that it is pitiless hunger alone which has driven them into this horrible custom. These miserable people are the chief pearl-divers of the Pacific; indeed, it is their only industry, and women and even children take part in it. There is at Anaa, says the writer, a woman who will go down twenty-five fathoms, and remain under water for three minutes. Nor was she an exception. The dangers of the work are great, for the depths of the lagoons are infested by sharks, against which the divers, being unable to escape, are forced to wage battle, in which life is the stake. No year passes without some disaster from sharks, and when one happens all the divers are seized with terror, and the fishing is stopped for a time. But gradually the imperious wants of life drive them back to the sea again, for mother-of-pearl is the current coin of the Tuamotu. With it he buys the rags which cover him, the little bread and flour which complete his food, and alcohol, "that fatal present of civilization," for which he exhibits a pronounced passion. Twenty or thirty years ago the trade in mother-of-pearl in the Tuamotu archipelago was very profitable for those engaged in it. For a valueless piece of cloth, a few handfuls of flour, or some rum, the trader got half a ton of mother of pearl worth one or two thousand francs, or even fine pearls of which the natives did not know the value. The archipelagoes were frequented by vessels of all nationalities: mother-of-pearl was abundant, and pearls were less rare than they are now. The number of trading ships increased: there was competition amongst them, and consequently a higher price to the natives, who fished to meet the new demand with improvident ardour. The consequence is that the lagoons are less productive, and that even the most fertile give manifest signs of exhaustion. The prospect of having the inhabitants of Tuamotu thrown on its hands in a state of helpless destitution, as well as of the disappearance of the principal article of the trade of Tahiti, and an important source of revenue to the colony, alarmed the Colonial administration and the Ministry of Marine and the Colonies in Paris. Accordingly, M. Brandely was selected to study the whole subject on the spot. The points to which he was instructed to direct special attention were these: (1) The actual state of the lagoons which produce oysters; are they beginning to be impoverished, and if so what is the cause, and what the remedy? (2) Would it be possible to create at Tuamotu, Gambier, Tahiti and Moorea, for the cultivation of mother-of-pearl, an industry analogous to that existing in France for edible oysters? Would it be possible by this means to supply the natives of Tuamotu with continuous, fixed, remunerative labour which could render them independent, and remove them from the shameless cupidity of the traders? Could they not be spared the hardships and dangers resulting from the continued practice of diving, and be turned to more fixed sedentary modes of life, by which they might be raised gradually in the social scale? (3) Should the pearl fishing in the archipelagoes be regulated, and, if so, what should be the bases of such regulations? It was on the mixed economical and philanthropic mission here indicated that M. Brandely went to Tahiti in February last. The statistics did not show any decline in the production of mother-of-pearl, but a careful study on the spot showed that this was due to the great amount of the clandestine traffic, and that the lagoons were growing less productive day by day, that beautiful mother-of-pearl was becoming rarer, and in order now-a-days to get oysters of a marketable size, the divers are forced to go to ever greater depths. M. Brandely recommends prompt and vigorous measures be taken at once, as the lagoons of Tuamotu will soon be ruined for ever. The partial steps already adopted have been useless. The total prohibition of fishing in some of the islands for several years has failed, because it has been found that the pintadine is hermaphrodite, and not, as formerly was believed, unisexual. The cause of the impoverishment of the lagoons is excessive fishing, and nothing else. He thinks that it is possible to create in Tuamotu, Gambier, Tahiti and Moorea a rational and methodical cultivation of mother-of-pearl oysters, analogous to that existing with regard to edible oysters on the French coasts, and to constitute for the profit of the colony an industrial monopoly which no other country can dispute, for nowhere else can such favourable conditions be met with.—*Nature*, 9th April.

RAVAGES OF RATS AND BATS IN COCONUT TREES.

(*From Annual Report of the Jamaica Public Gardens and Plantations for the year ended 30th September 1884, by D. Morris*, M. A., F. L. S., *Director.*)

Numerous letters have been addressed to me on this subject; and, in addition to this, I estimate that at the Palisadoes Plantation under my charge during the late drought, the losses caused by rats amongst coconut trees amounted to nearly £100 per annum.

Dr. Ferguson of Port Maria reports the destruction caused by rats on his extensive coconut walks as "immense;" and the subject has necessarily occupied his attention for some time; while numerous other correspondents speak in similar terms.

The question of protecting coconut trees from the attacks of rats is therefore a matter of considerable importance, and with the view of contributing something towards this end, I have lately been in communication with coconut planters in different parts of the island, and from the replies received I select one or two, which, as the result of practical experience, will no doubt commend themselves to careful consideration. The first of these replies is from Mr. Joseph Shearer, Vale Royal, Duncans P.O., and is as follows:—

"I got out in 1882 1,000 sheets galvanized iron 36 inches by 12 inches, they stood me with cost and charges £35 14s.; and 1,000 tin sheets of the same size, the cost of which was £28 7s. 10d. Although dearer at first, the zinc sheets are preferable, as near the sea the tin sheets soon become rusted. The rats were so bad in the coconut walks where I used these sheets that I reckoned they paid their cost fully the first year. In putting them on I nailed them flat to the trees with two or three sheating nails in each. If the coconut trees are very close together a rat can go from one to the other across the limbs, and great care should be observed that there are no ladders near by, such as a dry limb hanging on the ground, or a mangrove twig, &c., because if there be any such the rat will get up the tree independently of using the trunk, and the zinc or tin sheets would be of no use. It is useful if you cannot isolate all the trees at least to isolate clumps. Care must be taken, too, to dislodge the rats from the top before putting on the tin sheets. The best thing I have found for this is sandwiches of bread and phosphoric paste, deposited among the roots and fronds."

Mr. John Clark, Haughton Court, Lucea, writes:—

"The zinc sheets to protect coconut trees from rats have been tried here with good results; the rats that live in the trees must first of all be driven out of the trees or poisoned; the sheets must then be nailed round the tree, simply flat against the stem, low enough in the case of short trees, so that the rats cannot spring from the trunk below the sheet on to a limb that may be hanging down near the trunk, which they have been known to do. Rats have been seen attempting to pass over the sheets and failing.

"The sheets are zinc 42 inches by 12 inches, and apparently 1-32 inch thick, and cost about 8d. each in London. Tin sheets last no time and are not to be thought of. The nails for putting them on are ordered as 5dy. galvaniz d shingling nails."

It is very probable that Mr. Shearer's and Mr. Clark's plans which require only galvanized iron (not tin) sheets 36 inches by 12 inches and fastened perpendicularly on the tree by means of a couple of sheathing nails will commend itself for general adoption. These sheet cost, it will be noticed, delivered on the estate, at the rate of £35 14s. per thousand. This is a large sum to expend at once on coconut trees, but the bands are required only for bearing trees, and I quite agree with Mr. Shearer that where the depredations by rats are really bad the sheets will pay for themselves during the first year. With regard to the preceding remarks it is to be noticed that the rat which commits such damage in coconut trees is the black species, much smaller than the ordinary brown rat of the cane-fields. It is a splendid climber, and as it builds its nest in trees, it is beyond the reach of the mungoose, which is a very indifferent climber. As I have before remarked,* "it is only in the open, where cultivation is carefully kept up, and the rats have no special shelter or trees to climb, that the mungoose is a successful rat-killer."

In St. Thomas-in-the-East Mr. James Harrison informs me that he suffers principally in his coconut walks not from rats of any species, but from frugiverous bats (called by the negroes "rat bats," probably, as suggested by Goose, to distinguish them from butterflies to which they give the name of bats). Mr. Harrison finds the best plan to keep down the ravages of the bats "is to shoot them in the day-time whilst hanging in clusters on the trees."

* See "The Mungoose on Sugar Estates in the West Indies," by D. Morris, M.A., F.L.S., Jamaica, 1882.

COCONUT PALM (*Cocos nucifera*), LINNÆUS.
(*From "Origin of Cultivated Plants," by Alphonse de Candolle, 1885.*)

The coconut palm is perhaps, of all tropical trees, the one which yields the greatest variety of products. Its wood and fibres are utilized in various ways. The sap extracted from the inner part of the inflorescence yields a much prized alcoholic drink. The shell of the nut forms a vessel, the milk of the half-ripe fruit is a pleasant drink, and the nut itself contains a great deal of oil. It is not surprising that so valuable a tree has been a good deal planted and transported. Besides, its dispersion is aided by natural causes. The woody shell and fibrous envelope of the nut enable it to float in salt water without injury to the germ. Hence the possibility of its transportation to great distances by currents and its naturalization on coasts where the temperature is favourable. Unfortunately, this tree requires a warm, damp climate, such as exists only in the tropics, or in exceptional localities just without them. Nor does it thrive at a distance from the sea. The coconut abounds on the littoral of the warm regions of Asia, of the islands to the south of this continent, and in analogous regions of Africa and America; but it may be asserted that it dates in Brazil, the West Indies, and the west coast of Africa from an introduction which took place about three centuries ago. Piso and Marcgraf (*a*) seem to admit that the species is foreign to Brazil without saying so positively. De Martius, (*b*) who has published a very important work on the Palmaceæ, and has travelled through the provinces of Bahia, Pernambuco, and others, where the coconut abounds, does not say that it is wild. It was introduced into Guiana by missionaries. (*c*) Sloane (*d*) says it is an exotic in the West Indies. An old author of the sixteenth century, Martyr, whom he quotes, speaks of its introduction. This probably took place a few years after the discovery of America, for Joseph Acosta (*e*) saw the coconut palm at Porto Rico in the sixteenth century. De Martius says that the Portuguese introduced it on the coast of Guinea. Many travellers do not even mention it in this region, where it is apparently of no great importance. More common in Madagascar and on the east coast, it is not, however, named in several works on the plants of Zanzibar, the Seychelles, Mauritius, etc, perhaps because it is considered as cultivated in these parts.

Evidently the species is not of African origin, nor of the eastern part of tropical America. Eliminating these countries, there remain western tropical America, the islands of the Pacific, the Indian Archipelago, and the south of Asia, where the tree abounds with every appearance of being more or less wild and long established.

The Navigators Dampier and Vancouver (*f*) found it at the beginning of the seventeenth century, forming woods in the islands near Panama, not on the

mainland, and in the isle of Cocos, situated at three hundred miles from the continent in the Pacific. At that time these islands were uninhabited. Later, the coconut palm was found on the western coast from Mexico to Peru, but usually authors do not say that it was wild, excepting Seemann, (*g*) however, who saw this palm both wild and cultivated on the Isthmus of Panama. According to Hernandez, (*h*) in the sixteenth century, the Mexicans called it *coyolli*, a word which does not seem to be native.

Oviedo, (*i*) writing in 1526, in the first years of the conquest of Mexico, says that the coconut palm was abundant on the coast of the Pacific in the province of the Cacique Chiman, and he clearly describes the species. This does not prove the tree to be wild. In southern Asia, especially in the islands, the coconut is both wild and cultivated. The smaller the islands, and the lower and the more subject to the influence of the sea air, the more the coconut predominates and attracts the attention of travellers. Some take their name from the tree, among others two islands close to the Andamans and one near Sumatra.

The coconut occurring with every appearance of an ancient wild condition at once in Asia and western America, the question of origin is obscure. Excellent authors have solved it differently. De Martius believes it to have been transported by currents from the islands situated to the west of Central America, into those of the Asiatic Archipelago. I formerly inclined to the same hypothesis, (*j*) since admitted without question by Grisebach; (*k*) but the botanists of the seventeenth century often regarded the species as Asiatic, and Seemann, (*l*) after a careful examination, says he cannot come to a decision. I will give the reasons for and against each hypothesis.

In favour of an American origin, it may be said—

1. The eleven other species of the genus Cocos are American, and all those which de Martius knew well are Brazilian. (*m*) Drude (*n*), who has studied the Palmaceæ, has written a paper to show that each genus of this family is proper to the ancient or to the new world, excepting the genus Elæis, and even here he suspects a transport of the *E. guineensis* from America into Africa, which is not at all probable. The force of this argument is somewhat diminished by the circumstance that *Cocos nucifera* is a tree which grows on the littoral and in damp places, while the other species live under different conditions, frequently far from the sea and from rivers. Maritime plants, and those which grow in marshes or damp places, have commonly a more vast habitation than others of the same genus.

2. The trade winds of the Pacific, to the south and yet more to the north of the equator, drive floating bodies from America to Asia, a direction contrary to that of the general currents. (*o*) It is known, moreover, from the unexpected arrival of bottles containing papers on different coasts, that chance has much to do with these transports.

The arguments in favour of an Asiatic, or contrary to an American origin, are the following:—

1. A current between the third and fifth parallels, north latitude, flows from the islands of the Indian Archipelago to Panama. (*p*) To the north and south of this are currents which take the opposite direction, but they start from regions too cold for the coconut, and do not touch Central America, where it is supposed to have been long indigenous.

2. The inhabitants of the islands of Asia were far bolder navigators than the American Indians. It is very possible that canoes from the Asiatic Islands, containing a provision of coconuts, were thrown by tempests or false manœuvres on to the islands or the west coast of America. The converse is highly improbable.

3. The area for three centuries has been much vaster in Asia than in America, and the difference was yet more considerable before that epoch, for we know that the coconut has not long existed in the east of tropical America.

4. The inhabitants of the islands of Asia possess an immense number of varieties of this tree, which points to a very ancient cultivation. Blume, in his *Rumphia*, enumerates eighteen varieties in Java and the adjacent islands, and thirty-nine in the Philippines. Nothing similar has been observed in America.

5. The uses of the coconut are more varied and more habitual in Asia. The natives of America hardly utilize it except for the contents of the nut, from which they do not extract the oil.

6. The common names, very numerous and original in Asia, as we shall presently see, are rare, and often of European origin in America.

7. It is not probable that the ancient Mexicans and inhabitants of Central America would have neglected to spread the coconut in several directions, had it existed among them from a very remote epoch. The trifling breadth of the Isthmus of Panama would have facilitated the transport from one coast to the other, and the species would soon have been established in the West Indies, at Guiana, etc., as it has become naturalized in Jamaica, Antigua,—(*q*) and elsewhere, since the discovery of America.

8. If the coconut in America dated from a geological epoch more ancient than the pleiocene or even eocene deposits in Europe, it would probably have been found on both coasts, and the islands to the east and west equally.

9. We cannot find any ancient date of the existence of the coconut in America, but its presence in Asia three or four thousand years ago is proved by several Sanskrit names. Piddington in his index only quotes one, *narikela*. It is the most certain, since it recurs in modern Indian languages. Scholars count ten of these, which, according to their meaning, seem to apply to the species or its fruit. (*r*) *Narikela* has passed with modifications into Arabic and Persian. (*s*) It is even found at Otahiti in the form *ari* or *haari* (*t*) together with a Malay name.

10. The Malays have a name widely diffused in the archipelago—*kalâpa*, *kôpa*, *klôpo*. At Sumatra and Nicobar we find the name *njior*, *nivor*; in the Philippines, *niog*; at Bali, *niuh*, *njo*; at Tahiti, *nuh*; and in other islands, *nu*, *nidju*, *ni*; even at Madagascar, *wua-niu*. (*u*) The Chinese have *ye*, or *ye tsu* (the tree is *ye*). With the principal Sanskrit name this constitutes four different roots, which show an ancient

existence in Asia. However, the uniformity of nomenclature in the archipelago as far as Tahiti and Madagascar indicates a transport by human agency since the existence of known languages.

The Chinese name means head of the king of Yue, referring to an absurd legend of which Dr. Bretschneider speaks. (*v*) This savant tells us that the first mention of the coconut occurs in a poem of the second century before Christ, but the most unmistakeable descriptions are in works later than the ninth century of our era. It is true that the ancient writers scarcely knew the south of China, the only part of the empire where the coconut palm can live.

In spite of the Sanskrit names, the existence of the coconut in Ceylon, where it is well established on the coast, dates from an almost historical epoch. Near Point-de-Galle, Seemann tells us may be seen carved upon a rock the figure of a native prince, Kotah Raya, to whom is attributed the discovery of the uses of the coconut, unknown before him; and the earliest chronicle of Ceylon, the *Mahawansa*, does not mention this tree, although it carefully reports the fruits imported by different princes. It is also noteworthy that the ancient Greeks and Egyptians only knew the coconut at a late epoch as an Indian curiosity. Apollonius of Tyana saw this palm in Hindustan, at the beginning of the Christian era. (*w*)

From these facts the most ancient habitation in Asia would be in the archipelago, rather than on the continent or in Ceylon; and in America in the islands west of Panama. What are we to think on this varied and contradictory evidence? I formerly thought that the arguments in favour of Western America were the strongest. Now, with more information and greater experience in similar questions, I incline to the idea of an origin in the Indian Archpelago. The extension towards China, Ceylon, and India dates from not more than three thousand or four thousand years ago, but the transport by sea to the coasts of America and Africa took place perhaps in a more remote epoch, although posterior to those epochs when the geographical and physical conditions were different to those of our day.

LETTERS FROM JAMAICA: NO. V.

SUGAR ESTATES IN JAMAICA—A "BUGGY"—JAMAICA RIVERS—THE PALMY DAYS OF SUGAR—PORT MORANT—ECONOMIC PRODUCTS—SUGAR-MAKING—LIBERIAN COFFEE—JAMAICA DELICACIES—MIXED LABOR.

BLUE MOUNTAIN DISTRICT, March 1885.

To the Editor of the Ceylon Observer.

DEAR SIR,—Since last addressing you I have visited the eastern end of the island, and passed through the township of Bath, and some of the sugar estates in the famed "Plantain Garden River" district: a description of my journey will give me materials for my letter this month, and help your readers to while away a few spare moments in learning a little more about "Xaymaca," the land of wood and water.

I left this *plantation* on Saturday, 7th March (for in Jamaica a sugar property is an *estate*, but coffee land a plantation), in company with our stipendiary Magistrate and the Clerk of Petty Sessions, who kindly gave me a seat in their "buggy" as far as Morant Bay. These buggies are Americans, but the seats are not back-to-back, as in the Ceylon American waggon, but the same as a phæton except that the seat next the driver turns on a pivot so that it can be used either way. We rode from here to Monklands where the cart road commences, but it is very rough and stony, in fact there are no bridges or culverts, for there is not enough public money to make good roads all over the island; and moreover the river-beds are so broad, and shift about so with almost every "October" *season*, as the rains are termed, that bridges would have to be very long, and the expense too heavy: usually the rivers are low enough to be easily fordable, but of course the process is very trying to carriage springs.

To return to our Magistrate, for we have a "Petty Sessions" or Police Court at Woburn Lawn every fortnight, except during the rains, when the rivers between this and Morant Bay are impassable: they sometimes "come down," as the saying goes, so quickly that a traveller has been known to be penned in between two branches, having got over one arm, and finding the next impassable, turned to go back to the coast, but found the spot he had but a short time previously crossed too dangerous, so had to spend the night in his carriage between the two, in fear and trembling lest a further rise should flood his place of refuge, and sweep him away. I was shown a spot where stood the hut of five Calcutta cooly people who were all washed away and drowned in the floods of last October. A curious custom obtains here, that a person may refuse to be tried at the Petty Sessions for certain minor offences and choose the higher tribunal: this is very vexatious, as the District Court is generally a long way off. Monklands is a property which in the old slave days was one of the grandest coffee plantations, the proprietor luxuriating in gold plate, as was customary I am told on many estates in those old "palmy days" when sugar was £60 a hogshead and coffee 150s to 160s a cwt. if not even more. A story is told in this district of a celebrated robber and highwayman, one Three-fingered Jack, who stole a great deal of this gold plate and secreted it in a cave, buried in the dense woods of the Blue Mountain range, then even more inaccessible than at present: he was at last captured, hung, and gibbeted, but his treasure store has never been discovered. From Trinity Villa, which is a large village and district with a nice room, church and school, the road passes through and near *Coley*, *Serge Island*, *Belvidere*, and *Blue Mountain* (all sugar estates), on to Morant Bay, the capital of St. Thomas in the east, and celebrated as the spot where the rebellion of 1865 broke out, several Europeans were murdered, and the Court House burnt down over the heads of those who were gallantly defending it. Such a state of things, we trust, will never occur again, as the creoles were sadly misled, and have now a sad example before them in Hayti; and will have the good sense to see that their best and safest interests lie in loyalty to the Queen and old England.

From Morant Bay I had for cicerone the acting Inspector of Police, who had kindly timed his rounds to take me with him. We passed through *Lyssons* and other sugar estates on to Port Morant, a snug harbour, which reminded me of Galle on a smaller scale, and here the country up to and around Bath became much more like the environs of Kandy and Gampola, and quite tropical; we saw some Banana plantations, an industry which of late years has yielded good returns, as have also coconuts and oranges, while cacao is also beginning to be more extensively cultivated. The coconut trees though bearing fine large nuts, seemed to me less tall than those in Ceylon: this is probably due to severe gales and hurricanes. Bath is a long straggling street with a church and courthouse, and a good lodging house (there are no Government resthouses in Jamaica). I went round the old Botanical Garden which is now more of a jungle than anything else, as I believe it is now only made use of for the seeds borne by its fine old trees. At a

w Seemann, *Fl. Vitiensis*, p. 276; Pickering, *Chronol. Arrangement*, p. 428.

Dr. Major's I was shown cloves, nutmegs, cinnamon, and Liberian coffee : the nutmegs had an immense crop, but the trees were smaller than some I saw in a garden near Nilambe in the days of Louis Byrde. From Bath we passed through an old property named Suffolk Park owned originally by an old Cavalier Colonel, there being still extant a fine old tree planted by him : It is truly like an English park ; there were plenty of logwood trees, which are not unlike in appearance to large hawthorns ; the cattle grazing under these and other beautiful trees, on the smooth grassland, was quite a picturesque sight.

We were then close on our journey's end for the day, for we shortly afterwards entered that fine old sugar estate Hordley, owned now by Mr. James Harrison, who came out to the island quite a youth, and has been now 38 years in Jamaica, a fine specimen of a robust, hard-working and experienced sugar planter. We were shown over the works, which are celebrated for a wide undershot-wheel, and a light ironwheel, also undershot, but with elevator buckets that deliver water on to a staging, and so by a spout to supply the mill. We saw the process of sugar-making as well as rum : it is certainly not as attractive or as clean work as coffee curing, and I am therefore very thankful my lines have always been laid in the more pleasant work of coffee planting. Hordley though of great age, is still a very fine property, the soil being very rich and alluvial ; but prices are now so low that most sugar planters are only able with the help of *rum* to make both ends meet, profits being quite at a standstill. Going up the steps to the great house, where we were most hospitably entertained, we saw something in baskets and bags, which my friend said must be some sort of wild grape ; I observed that it looked more like very large coffee, and proved to be right for it was Liberian cherry ; I had never seen it in any quantity before. Next morning we visited the field where it was grown, but as I have never seen any other could not judge whether it was a fine specimen ; however, the trees were vigorous and bearing heavily, but evidently had not been pruned in accordance with the prevailing system on Ceylon coffee estates.

Next morning we journeyed back to Morant Bay by another road, and visited a cattle *pen*, named Pera, where we were also very hospitably entertained by the lessee, who regaled us on fresh oysters from off the "mangrove" roots, wood pigeons, stye-fed pork, tender beefsteak and cabbage palm, all delicacies not easily to be got upcountry save the tough beefsteak. This property lies [illegible] sea, and a stream passes through it, in which there are alligators, and there are also ponds in which wild ducks abound. En route homewards we went into Lysson's estate *works*, which are of more modern construction as to appliances, and I should certainly give them the palm ; the power was steam, and the centrifugal process can be used if desired, but most of the Jamaica sugar is Muscavado, and is refined in England or whatever country to which it is sent. At Lysson's we saw creoles, brown people, Bengal coolies and Chinese all working together harmoniously. Mr. John Wallace the very obliging overseer or superintendent of Lysson's told us his Chinese were now working very satisfactorily, for at first the sugar planters had much trouble with them, as they declared they had been promised a dollar a day on enlistment and refused to work for less ; whereas it was but one shilling a day on which the contracts had been signed. W. S.

PUBLIC OFFICERS AND LAND IN MAURITIUS.—A Circular Letter from Earl Derby, dated 2nd February, enjoined that in future no salaried public officer should be allowed to cultivate or occupy for profit, except through an attorney or agent, any land of greater extent than 20 acres, or situated at a distance of more than six miles from his residence ; but this rule need not be applied to officers already occupying estates or stock farms, unless such occupation should be found to interfere with their duties. No magistrate whose duty it is to adjudicate between indentured labourers and their employers should be allowed to employ indentured labourers in the district in which he exercises jurisdiction.—*Mercantile Record and Commercial Gazette.*

TROPICAL EXHIBITS.—The Colonial and Indian Exhibition Committee appointed in Brisbane, among other things, says in a circular that tea, coffee, spices, and other tropical and semi-tropical products will be important exhibits, and we entirely agree with the Committee. But as there can be no object in misleading people at home, it would be well that among the information forwarded concerning the cultivation of these products it should be clearly laid down that any persons attempting to grow them in Queensland will be compelled to do so with other than Asiatic labor. This will perhaps act as an inducement to some people to go into the cultivation of tropical products ; others ki may deter, but it is just as well to let the people know the truth.—*Mackay Standard*, April 3rd.

TEA PLANTING : THE WEATHER AND ITS EFFECT ON TEA—GROWTH OF PARASITIC FUNGI AND MOSS ON STEMS OF TEA.—LINDULA, May 15th.—There is a continuance of the weather previously reported : perfectly calm days with clear mornings, becoming cloudy about noon with thunder and showers of rain, which are not heavy and do not last long. While such weather promotes the growth and the flushing of tea, it is right to add that it seems equally to promote parasitic growths of mosses or fungi on the stems. To cope with this "enemy of the tea tree" at high altitudes, we have supplied the women-labourers with pieces of coir matting, with which they are rubbing the stems clean. Of course, a considerable proportion of buds will be rubbed away in the process, but that cannot be helped. We mean subsequently to give the cleaned bushes a good dusting with caustic lime. We advise tea cultivators in high damp districts not to neglect these stem mosses.

EFFECT OF PRUNING: PRUNED AND UNPRUNED VINES.—Long ago the produce of the grafted, as compared with that of the ungrafted Vine, was ascertained. No difference was preceptible. This is now received in France as an indisputable fact. The quantity of alcohol in the juice is in proportion to the sugar in the Grapes, and very often the wine is sold according to the alcoholic strength; that is to say, that a hectolitre of wine is sold for 2·50 or 3 fr. and more (according to circumstances), according to the alcoholic strength; wine having 10 per cent alcohol selling, for example, at 30 fr., while if it contains 12 per cent it brings 36 fr., and so on. Considering that the great merchants sell often 1,000, 2,000, or 3,000 hectolitres, it is seen that the question of alcholic strength (that is to say, the amount of sugar) is one of the greatest importance for them. The strength is estimated with care by well-known practical methods. In many southern departments the French Vines are now grafted on to divers American Vines, to protect them against the Phylloxera. The American Vines are varieties of Vitis æstivalis, V. cordifolia, and V. riparia, or of hybirds between them. The grafts succeed well; there are even schools of grafting, with hundreds of students, and grafting competitions are established in many departments. No doubt if the stock is badly chosen the graft does not develope well, and the produce is bad; but it is a fact that, in the South of France, grafted plants give quite as good results as those growing on their own roots. The results obtained on fruit trees, which immemorial practice indicates and recommends, are in fact of the same nature.—MAXIME CORNU, Jardin des Plantes, Paris.—*Gardener's Chronicle.*

THE JOHOR FORESTS: SOME CURSORY NOTES ON THEM,

BY JAMES MELDRUM, F.R.G.S.,

Commissioner to the International Forestry Exhibition at Edinburgh from H.H. the Maharajah of Johor, K.C.S.I., &c.

The Johor Forests are situated on the Malayan Peninsula, the extreme south of the Asiatic Continent. The territory of Johor, Muar, and their dependencies consist of about 10,000 square miles, and are bounded on the north by the native State of Pahang and the British Settlement of Malacca, on the south by the strait Salat Tambrau, on the west by the Straits of Malacca, and on the east by the China Sea. The thriving town of Johor Bharu is distant from Singapore fifteen miles across the strait and island; but going round by water it is thirty miles. Population, about 100,000 Chinese, and 50,000 Malays; very few Europeans. The aborigines of the forests on the Malayan Peninsula are few in number, and seldom seen. They lead a solitary and precarious life in the depths of the jungle, subsisting on fruits, roots, and the flesh of the wild pig, deer, *plandok*, and what birds they are able to kill. Sometimes they collect gutta and exchange it with the Malays for a little rice and tobacco. Their mode of dealing used to be to deposit at a certain place the products they had collected, leave them, and return hoping to find in their stead a quantity of rice, tobacco, or salt. They live sometimes in trees, sometimes in temporary huts on the ground, seldom remaining long in one place. They are called *Orang Utans*, or *Orang Sletar*. Their clothing generally consists of a piece of bark wrapped round the loins. They are very low in the scale of humanity. Another tribe are the *Orang Laut*, or sea-people; they are born, live, and die in their boats, which are of small dimensions. Skin disease is very common amongst them, owing to their eating so much fish. Dogs are always of their party; they are used for hunting the deer in the forests. Besides a *billyong* (native axe), a *parang* or chopper, and a knife, they frequently possess a *sumpitan* and poisoned arrows. Fire-arms they do not possess.

The climate of Johor is, for a tropical one, exceedingly healthy. The thermometer averages about 78° in the shade. This lowness of temperature is, no doubt, owing to the vast forests of the interior, which attract the rain clouds and retain the moisture, so that when the wind blows over them the breezes are comparatively cool. This is very observable to anyone who has travelled in the arid parts of India and China and other countries where the wind, when it blows over extensive barren tracts, comes heated as if from some fiery furnace, destroying and preventing vegetation, rendering what were once fertile lands wholly uninhabitable. The indiscriminate destruction of forest trees will soon ruin any tropical or sub-tropical country, and we may rejoice that, in British India at least, the Government has taken much interest in forest administration and established conservators, having a staff of excellent and efficient officers in each of the presidencies in India. I might add, thanks are due to Colonel Michael, Dr. Cleghorn, and Dr. Brandis for their exertions in helping to bring about the establishment of a systematic forest department in India. The effect of the preservation of the forests that still remain, and the re-foresting that has been accomplished, will in time tell on the climate, and prevent the recurrence of the droughts that bring on those dreadful famines that have been of periodical occurrence ever since we knew India. His Highness the Maharajah of Johor has taken some steps towards the protection of his forests, and it is a condition stated in all contracts for land for any purposes, that a certain portion of forest is to be reserved. The soil on which these forests grow varies not a little according to locality; that near Johor Bharu is of a red colour, owing to the presence of iron; it is of the same nature as that of the island of Singapore. Towards the north it improves to a deep chocolate and brownish-black colour. Laterite near the town, granite towards the east and north-west.

Kaolin, white clay, decomposed granite, is found at several places; excellent dark-coloured clays are near at hand. One kind when found, is soft and plastic, and easily moulded into shape. After exposure to the air it becomes hard, like marble; it is greyish, having dark and red streaks through it.

Planters from Ceylon have recently settled in Johor. They are cultivating tea, which is turning out to be of an exceptionally good quality, owing, doubtless, to the adaptability of the soil for its growth. Coffee of the Liberian sort appears to flourish. Cocoa is doing well, and likely to be a success. Cinchona and cardamoms are all being tried, whilst an Arab gentleman is fortunate enough to have pitched upon soil suitable for sugar cane. Sago *(Sagus farinifera)* in Johor exists principally on the low lands, on some of the fresh water rivers. Its cultivation is not costly; only it does not yield a return under six or seven years, but after that its yield is constant. It springs up like the banana, after the ripe stem has been cut down. Its preparation is simple. The tree is cut down, and split in two halves longitudinally; the pith scooped out and washed in water, when the farina falls to the bottom. When sufficiently settled, the water is run off; the residue is then dried, and appears as flour Tapioca is cultivated.

The fruits of the forest are numerous. Chief among them is the *durian*, and to those who can overcome the peculiar odour, it is ever welcome and eagerly longed for. In taste it resembles the finest custard. The Malays consider it their finest fruit, and ascribe various virtues to it; they are passionately fond of it. The proper termination to a *durian* feast is to finish off with a few mangosteens—a delightful fruit of a sub-acid nature, with a pleasant flavour and smell. The *durian* tree is a large one; it bears at the age of seven or eight years. It is only to be found on the Malay Peninsula, Borneo, and the other islands of the Eastern Archipelago. Early navigators called the Straits of Malacca the Straits of Durian.

In scarce seasons, a durian fetches half a dollar, about 2s.—a long price for natives to give. When plentiful, they range from 10 to 20 cents—say, 5*d.* to 10*d.* each.

Many of the fruits of the forest trees are edible, and are made use of by the aborigines. Some are very palatable.

The mangrove flourishes wherever salt or brackish water flows; there are various kinds, most plentiful near the mouths of rivers and as far up as the influence of the tide goes. It is useful for fuel, and its bark for tanning and dyeing. Its fruit is not edible, to the great regret of the native, who says if he could only eat the fruit of the mangrove, and as he can always catch fish, his lot in life would leave nothing to be desired.

Coconut (*Cocos nucifera*) and other palms grow in various places on the coast and up the rivers. There is a beetle very inimical to the coconut palm, and, unless found and killed, totally destroys it.

Bamboos thrive wherever planted, but they do not exist in large clumps, as in India, Burma, and China.

The Malacca cane is found everywhere in the forest; like other ratans, it climbs trees, descends again, runs along the ground, and perhaps ascends another. There are a number of different kinds of ratans or canes, some no thicker than a quill, others thicker than a good-sized walking-stick. The Malays make use of the ratan for a number of purposes; with it they fasten the leaves composing the sides and roofs of their houses, tie on their axes to their helves, and their oars to their boats, whilst for hauling the logs out of the forest, and serving as cables for their rafts, nothing comes handier than the ratan. Indeed, it is a fail-me-never to the native.

Gum-dammar, or da-mar as the Americans call it, exudes from a large tree called *kruen*. It is got in the shape of oil, by notching the tree and kindling a fire at the bottom of it. This oil is used for painting the bottoms of boats; with the addition of lime, it is used as a putty for caulking the seams and decks of boats. The gum-dammar is made into torches, and also is used with coconut oil for caulking the seams of vessels. Much is exported to China and America, where it is manufactured into a low kind of varnish. It is cheap, and may be bought from a penny per pound upwards. There are some very clear and valuable gums, but this trade is not prosecuted as it might be.

Various barks and roots are found, some of them the natives boil, and give the decoction to those suffering from fever, dysentery, &c.

Those roots are generally very bitter, and it is probable that, if examined by a competent chemist, they would be found to possess medicinal virtues of no common order.

There are numberless patches of cleared land, now covered with strong crops of lalang grass for no use whatever apparently. These have been abandoned as gambier and pepper plantations. The Chinese cultivators do not use manure, because it is scarce and far to carry, so after exhausting the soil, they seek for fresh forest, where they begin anew to fell, burn, and destroy, then plant gambier and some pepper, and repeat the operation of taking all the pith out of the soil, and so go on from generation to generation. Those patches are everywhere met with within reasonable distance of water, and might easily be utilised for the cultivation of tea or other products, after they have lain fallow for some years.

Nearly the whole of the interior of Johor is dense virgin forest, and as there are no roads beyond a short distance from the sea-board, and from the banks of the rivers, there is no likelihood of the wealth of timber, now locked up, being available, as it is well known that timber beyond a certain distance from water carriage will not pay the expense of cutting and haulage. Near the banks of the river, for some distance inland, the land has been denuded of timber, principally by the Chinese, whose clearances are of a wholesale character; all falls before their axe; when sufficiently dry the wood is set fire to, and everything is consumed. On the land so cleared gambier (*terra japonica*) is cultivated, and generally a quantity of black pepper, the vines being manured by the spent leaves of the gambier. Two-thirds of all the gambier exported from Singapore is raised on the Johor territory. Each gambier plantation has its own cooking place, so that a large patch of forest is required for firewood used in the manufacture, which is of the simplest kind; the leaves are boiled and the juice inspissated poured into shallow moulds when it congeals, it is then cut into cubes about an inch square, put into bags and sent to market where it is generally repacked, pressed and is then ready for shipment. It is used for tanning, dyeing, dressing silk, and a little is used in medicine. Both gambier and pepper have risen in price of late. Great Britain and her Colonies, America and the Continent of Europe are the principal markets.

The magnitude and grandeur of those forests, viewed from the summit of a mountain called Gunong Pulai about twelve miles from Johor Bharu, fills the mind with a feeling of something approaching to awe. It is no exaggeration to say that there exist millions of trees of all shades of verdure; there they grow in silent solitude, there they spring up, attain to hoary old age, drop, and decay, others taking their place, and running their course in rapid succession. The sizes of these trees vary greatly, and are, generally speaking, from 1 to 6 feet in diameter, and from 80 to 150 feet high. Specimens of 350 kinds are in the Forestry Exhibition. The useful kinds are extensively used for local works and for exportation; China, India, and Mauritius being the principal markets, but considerable parcels are sent to the Dutch Colonies, Batavia and other parts of Java, and to Sumatra, Australia, New Zealand and other places. Little has been sent to Europe as yet: the difficulties are cost of freight and prejudice against using a new kind of timber. Sooner or later a trade will be done in some of the best kinds, such as *ballow* (sometimes called Johor teak), and camphorwood, both of these sorts having been admitted by Lloyds for all parts in ships of the highest grade. For purposes where great strength is required the first is excellent, and for durability the camphor is not to be surpassed. This is the *Kapur Kapor* of the Malays, and yields a gum and an oil. The gum is highly esteemed in China, where it is sold for more than its weight in silver, that is, the best quality of it; the inferior kinds range from 5 dollars to 50 dollars per catty (1⅓ lb.). It is not every tree that yields gum or oil, hence its costliness. The natives of the Malay Peninsula use a peculiar language whilst searching for the trees containing this precious substance. It is a large tree, sometimes measuring 6 feet in diameter, and attaining a height of 120 feet. It is known to scientific men as of the order *Dipteraceæ* classed as *Dryobalanops aromatica*, and is not to be confounded with the *Camphora laurus*, which is more a shrub than a tree, the champhor of which is obtained from the leaves and roots by boiling. On cooling it solidifies. This is about fifty times cheaper, and is what we get in the shops in this country. It is the product of Formosa, China, Japan, and Cochin China. It readily evaporates. The *Kapur Barus* does not, it being a natural gum.

It ought to have been noted that the *Ballow* is not yet classified; it appears to be a link between teak and greenhart; partaking of some of the best qualities of both. It has been greatly sought after and is now becoming scarce and dear.

At one time a species of *Hopea* was very abundant. It is a good useful wood, and at present a great variety of sorts of the same order are being sold under the name of *Serayah* or *Serai*. It still exists in quantity in the interior of the forests, but all near the banks of rivers have disappeared either from the ruthless clearing of the Chinese planter or the axe of the Malay wood-cutter. It yields good planks for house building and general purposes, masts and spars.

It is also known as Johor cedar. *Billian* and *Kranje (Dialivonindcum)* are most durable woods, but no longer to be had in quantity.

Mirabow (Afzelia palembanica) is an excellent wood, and is used for furniture and ship-building. It is easy to work, and, like the others already mentioned, stands a great breaking strain, and is also proof against the attacks of white ants. It polishes well.

Ebony, slow of growth, is small and scarce. *Ballow Bungah*, a yellow wood with some figure, is adapted for furniture-making. *Buntangor*, or *Poon* (*Calophyllum inophyllum*), good, useful wood, not so hard or heavy as the foregoing kinds, is extensively used for masts, spars, scaffolding poles, &c.

Byass, brass brass, mangas, meranti puteh, and a hundred others, are too soft for general purposes, but perhaps all of them might suit for convertion into pulp for the paper-maker, who, when he visits Johor, will find an unlimited supply of raw material at a very low cost.

There are many sorts of the same species. The tree called *madang* comprises *madang serayah, katanda, sisik, tandok, trawas, kumyit, paow, putih, batu, barang, possah, sama, koh, kladi*, and *aboo*.

Meranti, a soft poon, varies in colour and quality; of it there are half a dozen sorts.

Maraboo lan and *Chungal* are impracticable woods, very difficult to saw, but easily wrought with edge-tools. They bend a long way before breaking, suggesting their usefulness for gig shafts, carriage poles, fishing rods, &c. *Daroo*, a *dopytes* species has an agreeable smell, stands well if kept all dry or all wet.

The forests contain timber trees adapted for house and ship-building and general purposes and some kinds admirably suited for railway sleepers; these could be supplied in large quantities at various prices. The costlier kinds would last for a generation; some of the best sorts are almost indestructible. Nowhere could such a variety be obtained suitable for use on Indian railways.

It is desirable that the Johor timber trees should be named and classed botanically. No botanist has ever spent much time in Johor, so an interesting field is open to the first who goes there.

The sea-worm, or *Teredo navalis* like the *Xyaphaga dorsalis* in salt water, and the white ant (*Termite*) on shore, are the two chief agents in the destruction of timber within the tropics. The first attacks wooden ships, and indeed all wooden craft, piles, &c., unless sheathed with copper or some other metal. It lives wherever the water is brackish. It enters timber when young, making a hole no bigger than a pin point. It rapidly grows and increases in numbers until it attains the size of one's little finger, and measures from 6 to 9 inches long. By the time it arrives at these dimensions, the tree, boat, or ship in which it has been committing its ravages must sink to the bottom of the ocean. They are not long-lived. It is said to be hermaphrodite, and, like many other low forms of life, is very prolific. A writer in "Woods and Forests" says a single one deposits from one million to three millions of eggs in a season. Rain or fresh water kills them. Their bodies resemble the com-

mon earth-worm in some degree; they are very soft, scarcely bear handling. On their head is a shield as hard as shell, with which they bore their way through the hardest woods. The *Orang laut* esteem them a delicacy. The white ants, though small, are to be found in the forests and in every place where they can find timber suited to their taste. They are not particular what it is they attack—everything short of iron or stone. If the wood they come to be hard or of a description they do not like, such as teak, camphor-wood, or *ballow*, they merely nibble a little at the heart and depart to seek something more toothsome or agreeable to the palate. When they come upon a soft wood tree or pine-wood box containing clothes, books, &c., the havoc they do in a very short time is astonishingly complete. Frequently they are found where least expected; a wardrobe may be opened, and, to the surprise and loss of the owner, may be literally swarming with white ants, whose voracious little maws may have entirely destroyed whole suits of clothing, shoes, and all. I have seen the bottom of a tar-barrel entirely eaten away, and the beams of a house devoured so that only a thin skin remained. Various stories have been told of their eating up rupees and dollars, leaving nothing, not even the boxes!

There are a great variety of kinds and sizes of ants in the forests, from the little red fellow, barely visible, to the big red soldier ant, whose bite it is not in the least desirable to feel.

Birds are not numerous. Snakes and monkeys destroy the eggs and young ones. Tribes of monkeys used to visit the vicinity of Johor Bharu, and on Sundays when the saw-mills were not at work and all was quiet, they gained confidence and approached near the houses. It was interesting to watch their gambols, and their agile and graceful bounds from the branches of one tree to another, chattering and screaming the while, calling forth a deal of merriment, especially when, after hanging a while by the tail, they suddenly swung themselves upwards or downwards, landing on an adjoining one ten or fifteen feet away.

The forests yield also bamboos, canes, ratans, reeds, barks, fibres, and fibrous substances, materials for paper making, gums, resins, indiarubber, caoutchouc, various dyeing and tanning substances found in woods, roots, flowers, leaves, &c., wood oils, drugs, charcoal, timber, and various fruits and seeds. Guttapercha, or, as the Malays call it *getah taban*, was first discovered, or at least first brought into use, from the Johor forests. It was a fortunate thing that just when the telegraph was brought into use guttapercha appeared in the market from those forests. Nothing has been found better adapted for covering deep sea cables than guttapercha. As the tree is destroyed in obtaining the gutta, it is now getting scarce and very costly. It would be well for either the British or Johor Government to plant this invaluable tree, the gum of which may be put to so many uses.

Tigers are far from being scarce; they kill not a few Chinese gambier-planters and others during the year. H. H. the Maharajah offers fifty dollars for each tiger killed and brought in. There is a courageous Malay, an old man now, who takes his son with him when he is told of the whereabouts of a tiger, and who is very successful in killing them; he places two loaded guns pointing across the path the tiger takes, a string is fastened to each trigger, and as the beast goes along trailing his feet with cat-like motion, he trips on the string, off goes the gun, and he is invariably shot through the body just behind the foreshoulder.

A foreign gentleman who paid a visit to Johor might have killed one, but did not. One evening just before sundown, the green-eyed monster came behind my house on the verge of the forest and growled a growl, deep, hollow, vicious. My visitor, who had gone to Singapore, was surprised of the circumstance when he returned. He said "Ah! I vish I had been here, I vould have shot it." I said: "perhaps he may come again." Said he "Ah! I vish he vould, I vould shoot." Just about the same time, sundown, next evening, we heard a most terrific roar, making our hair stand on end and our blood curdle. I said: "Oh! there is the tiger." "Ah! give me your rifle, give me your rifle, I vill shoot," said my visitor. I replied: "Now, do not think about it, let him go; the jungle is very dense, it is getting dark, and you may be taken at a disadvantage; do not go." "Yes!" said he vehemently, "Yes! I vill go, give me your rifle." So, to please him I gave him my rifle, and instantly went into another room to get a spear and accompany him, thinking that he had a chance of coming off second best. I was not long in getting the spear, and made haste to run after him, but, to my astonishment, I had not far to run, for there was my foreign friend perched a stride, legs across the ridge of the roof of the cook-house, calling out in rather agitated tones: "Aha! Mosieu tigre, Mosieu tigre, come on, I vil shoot." I laughed just a little, but my visitor did not see anything to laugh at. He deliberately descended, politely gave me back my rifle, and said that "tigers were very cowardly brutes."

One day a tiger seized a wood-cutter by the right arm whilst at work in the forest, his wife was by good fortune near by, she instantly laid hold of her husband's left hand, and whilst the tiger pulled one way she screamed and pulled with might and main the other way—the tiger—whether from fright or in deference to a lady relaxed his grip, gave up the contest and retreated. I have on two occasions seen the bodies of wood-cutters brought in who had been killed by tigers, both had their right arms torn off at the shoulder. I suppose when the poor fellows became aware that a tiger was upon them they instinctively threw up their right arm to defend themselves.

Elephants used to be found not far from the town of Johor Bharu, but they are getting shy of the clearings now, and to get a shot at an elephant one must go beyond the Gunong Pulai Mountains or up the rivers Batu Pahat or Muar. They are not of the largest breed. No attempt has been made to tame them for work, as in India and Burma, where they work in the saw-mills, each one doing the work of 50 coolies.

Wild cattle exist; they are sometimes shot in the Muar district; their scent is very keen, sight and hearing acute to a degree, so it is difficult to get within range of them. If one is "below the wind" the smell of a herd may be felt although they are not visible. They are adorned with large horns.

The Johor steam saw-mills are situated at the edge of what was once dense forest; now all around is clear of timber and the town of Johor Bharu is becoming quite an important little place, with its streets of brick and tiled houses inhabited by Chinese and Malays principally. Those mills were established in the year 1859-60 and have gradually increased their plant until they may be pronounced the most extensive concern of the kind in Asia. His Highness the Maharajah of Johor gave facilities and encouragement to a few private individuals to set them agoing, and from their foundation up to the present time large quantities of manufactured timber have been shipped to China, India, Mauritius, Java, Ceylon, &c., besides supplying local demands. Ships of all nations have loaded at the mills, and as they lie at a jetty where there is deep water, there are facilities for loading with despatch. The machinery and engines are all from the best makers, Messrs. McDowell & Sons, of Johnstone, having supplied by far the greater part, which has given full satisfaction. The largest frame saw takes in a log 5 feet diameter. The planing and moulding machines and band saws are all in good working order, enduring the tear and wear of upwards of twenty years exceedingly well. To give some idea of the quality of the water of Johor, it is found that when the boilers are cleaned out, the insides of them are as clear and smooth as a sheet of paper. Any matter is washed off without difficulty. No use has been found for the vast quantities of saw dust daily thrown away. Wood only is burned, the fuel being rinds, saiabs, ends, &c. The sawdust is not utilised in any way.

Malay wood-cutters are employed to go to the forests and bring the timber in rafts to the mills. A company of six to ten is made up (they are generally friends and relations), a headman is selected and he his held generally responsible for the advances or money that are made to them. A sum is paid down when the agreement is made; with this money they purchase a boat and lay in a stock of provisions, tools, &c. In a month the headman makes his appearance and receives another advance, reporting progress; this is repeated three, four, or five times according to the size of the raft they mean to bring. Some

times six months or more elapse before the raft is brought to the mills, there being many contingencies that interfere with regular work—the habits and customs of the Malays, sickness, rainy weather, and sometimes want of rain sufficient to float the logs out of the small streamlets into which they have been rolled or dragged. Wives and children accompany their husbands and frequently lend a hand in hauling or rolling the logs out of the forest. They live in the jungle in huts when the trees are being felled, and in huts on the rafts when they are made up and in huts on the mills. They are a quiet, orderly people now; very independent, yet kindly disposed. Their wants are few, as thay do not suffer the privation attendant upon the rigorous and changeable climate of more northern latitudes. Theirs is a constant summer, monotonous perhaps in its sameness, more or less relaxiug, nevertheless very pleasant and enjoyable to them. They take nothing intoxicating, and are very fond of liberty and independence, and a free and easy life.

They Malay Peninsula offers to the Chinese a good field for immigration. No fewer than 120 small settlements have been made in Johor by them during the last year. The periodical droughts, brought on in no small degree by the absence of forests in China, cause famines, which induce many to leave their country. Coupled with the superabundant population, there is a steady stream of immigrants at all times, but these are not wanted in the Dutch Colonies nor in California or any of the United States. Neither is their presence palatable in Queensland, Australia, nor in New Zealand. It may be asked, where, then, are they to go? It may be answered, to the Malay Peninsula, where thousands will find employment in tie mining and in cultivating pepper, gambier, and other tropical products. It it is said that the land near the seaboard and on the banks of the rivers will soon be taken up, the answer is, make roads, and, above all, make railroads; this would open up the Malay Peninsula sooner than any other way, as the land on either side of a line of railway would instantly be taken up by rich Chinese and European capitalists. And here it may be added that it is not the fault of H. H. the Maharajah of Johor that a line has not long ere this been put through his territory. He has spent a large sum from first to last in making the attempt; doubtless he will be recouped when a railway through Johor is an accomplished fact. I think it was Sir Macdonald Stephenson who said that the day would come when there would be a railway across the Continent of Australia which would join one from Singapore through the Johor territory and up through the Malay Peninsula and British Burma on to Calcutta, and thus enable Australians, New Zealanders, Dutch, Spanish, French, and other colonists to go home per rail in a very short time. Of course he had the completion of the Euphrates Valley Railway in his mind's eye.

Nowhere could a railway be made cheaper than through the Johor territory. Land could be obtained on easy terms, sleepers of excellent quality could be had all along the line, Chinese labour is abundant. The opening up of Johor would benefit Singapore trade and commerce. The accomplishment of this is only a matter of time.

His Highness the Maharajah is an enlightened prince, a K. C. M. G., K. C. S. I., and is decorated with other foreign orders; he is anxious to do all he can for the advancement of his people and country. Under his mild but firm rule great strides have been made, and doubtless there exists a great future for Johor.—*Singapore Free Press.*

BRAZIL.—The Pernambuco planters have memorialized the Chambers for an emancipation law. Five years is the term, but they also want a gigantic bank to loan money to them at 6 per cent. interest and 6 per cent. sinking fund.—*Rio News.*

SULPHIDE OF POTASSIUM.—In support of his previous testimony with regard to the efficacy of the substance in checking the ravages of mildew and allied forms of fungus growth on plants, Mr. Tonks, of Knowle, Warwickshire, recently sent to our office a fine healthy specimen of a zonal Pelargonium which a month ago was rapidly perishing from the disease. This plant had been totally immersed, soil and all, in the solution, to complete cure of the malady.—*Gardeners' Chronicle.*

ARECANUT CULTIVATION.

(*To the Editor of the Local "Times."*)

SIR,—In now sending you, as promised, some further data, in reference to areca cultivation, I take advantage of Mr. Borron's letter (see page 791) categorically, as numbered, to add my mite to the valuable information he has given, and shew how far difference of locality may justify divergence of opinion under certain headings, omitting notice of those that agree with my own experience, that I cannot add to, or where it seems unnecessary.

(2) To the uses enumerated, as stated elsewhere, I should hope there is a fair prospect that, when grown on a large scale—the nuts cleaned and cured for export—a profitable market will be found for the prepared husk as with coconut. The shed leaves seem also to contain a fibre that might perhaps be turned to some account.

(3) To obtain the best results I quite agree, and think all points to it, that a "not low, and as well as possible distributed rainfall" is a desideratum. In the Udagama district, even during the disastrous drought of last year Mr. Borron refers to, I do not think on any occasion a fortnight passed without an appreciable shower—vegetation of all kinds, I might say, remaining entirely unaffected by it. On the other hand, on journeying up the line to Dikoya last month, the effects of a protracted interval of unbroken sunshine, either at the time, or previously (or both?) seemed to me painfully apparent on many well-aged clumps of areca about and beyond Kadugannawa, as far as Nawalapitiya—a wetter neighbourhood, I should suppose, than Matale East.

(4) I find the palm grows very well on steep features. If necessary, the injury referred to might be effectually checked by a modified system of terracing at a not prohibitive outlay.

(6) As to the effect of quartz in the soil I am unable to speak, as it hardly occurs here. Under otherwise favorable conditions, "the better the soil the better the growth and crop," I take it may be regarded almost generally, for all cultivation, as a truism.

(8) Slab rock certainly should be avoided, though in an evenly moist climate, where there is some shade, and with an appreciable top dressing of good soil, good growth and crop may, I think, be looked for—I mean in a clearing where a bit of ground of this description occurred on which jungle trees had grown up I would not hesitate to plant it over, leaving additional shade. On rocky land, and amongst soil-retaining boulders, that the areca grows luxuriantly, and fruits very heavily—possibly better than in any other situation, whatever the features of the land may be otherwise—I can vouch for, *in a suitable climate.* Under protracted drought no doubt the rocks would absorb and give off again an amount of heat that might be even fatally injurious.

(9) My experience here is quite the reverse. Six months old plants have hung fire and been a failure, whilst seed at stake (better to be well germinated) have proved an unvarying success on all the estates in this district.

(10) That it is *absolutely necessary to success* to keep an areca clearing "systematically clean of all jungle stuff, &c.," there is abundant evidence to the contrary. But, as to whether as a matter of choice, this may, or may not be, the best system to adopt, I would prefer reserving opinion for the present. Anyhow, that but light outlay is necessary under this heading, and that a far less systematic, costly, system than in vogue for coffee, &c., will be found to answer very well is, I consider certain.

(11) I need not reiterate my belief in favor of a closer system of planting than Mr. Borron recommends. The crowded clusters of fine trees, bearing crops certainly on an average beyond his estimated yield of 300 nuts, to be seen in the native gardens about here, afford all the evidence necessary. If it is argued that this is no fair criterion—that the trees will not bear thus beyond the charmed influence of the human voice,—I can only reply that granting the need, I will shout at my trees till they do, if manuring means this, for the crop allows ample margin! At the same time, I could also shew Mr. Borron more than one not inconsiderable patch growing wild and bearing well in the jungles near here. On some land belonging to Mr. Dobree there is a sort of cave on a rather steep rocky bit of ground of which in

olden times (and hence the arecas!) some outlawed chief is said to have made a hiding place, where amongst the heavy original forest around there are any number of trees, thickly growing, that I have seen myself in heavy crop, the which some villager, I believe, annually purchases and picks. Many of the trees have grown up so long and thin in their struggle for the light, raising their heads above the forest trees, that it is impossible to gather from them. This instance gives evidence also against as a necessity, systematic cultivation.

(13) The plant may be, as Mr. Borron says, a greedy surface-feeder; but, though the fact seems now disputed by the authorities as to the power of certain, or any, plants to absorb nitrogen, I cannot help leaning to the belief that the areca does thus derive much of its nourishment from the atmosphere. I have a few well-grown arecas and tea plants growing together without apparently much interfering with one another; and Simmons in *Tropical Agriculture* speaks of the former as used as a shade-tree for cardamoms by the natives in parts of India—forming thus a dual cultivation.

(14) I would endorse all Mr. Borron here says. The only thing that might be added is that in the low country, where the climate is a moist one, the tree will be found to arrive at maturity, I should say, at least a year sooner than elsewhere, much however, depending on the soil. I believe it is a fact too, that, though I cannot but in one instance speak on positive evidence, under especially favourable circumstances, the varieties, I gather, peculiar to the lowcountry are often in good crop at the 4th year, a year earlier anyhow than the common Ceylon species.

(17) True!

(21) Besides the common Ceylon nut (the Sinhalese puwak), there are not *one*, but *two* varieties known here—the "hamban" and "rata" puwaks.

(22) I am glad I can now give you some additional information as to the market values in India, as it is a very important point, in fact an essential one, if the enterprize is to be developed beyond local demand. I have received a letter from an Indian house in reply to my request, in which they quote the present current rates as follows:—

Sheriwardhun	R38 to R40	per cwt
Bassein...	R30	
Southern India	R27	"
Goa, and other produce.	R22	"

but I am in doubts as to the "other produce" including Ceylon.

It takes 10,000 nuts on an average to a cwt. (I believe rather less than more for the better kinds), which, on Mr. Borron's figures of 480 trees (10′ × 10′!) only, and 300 nuts per tree, gives 15 cwt. per acre. Suppose the produce to be from the first variety, and, though at Mr. Borron's estimate of yield, the gross stand at R600 per acre?

(23) I have not yet met with, or heard of, any disease.

(24) A Government matter!

(26) After a lot of trouble I succeeded lately in procuring a few thousand Sheriwardon nuts from the native dependancy the place is in. These arrived in good order, and, as far as I know, have all grown. The price I had to pay for these nuts, selected ripe in the husk, especially for seed, was R22 per 1,000 on the spot, beside some rupees on this for expense and freight. It is so late in the season now that I fear more may not be procurable till September next, but I am willing to help anyone interested; and, as a matter of business, to book orders directed either to Messrs. Hayley & Co., Galle, Messrs. Creasy & Co., Colombo, or to myself at 10 per cent, on the above price (R22) and expenses; and will endeavor to have them supplied at once, or failing this as soon as possible.

Taking this para as an advertisement, please charge me for it.

Udagama, March 25.

Sir,—In my last letter the concluding sentence in (22) was meant as an emphasized fact—one impossible to be gainsaid, unless on the shewing that 15 cwt. per acre does not represent, and is materially in excess of, Mr. Borron's estimated yield; or unless my correspondent in India has misquoted the correct price given, which is but remotely probable. Accepting the latter as correct, the following tables, roughly calculated, may help to shew more clearly the position of the enterprize under each quotation, (1) on estimate of *15 cwt.* elsewhere it would seem accepted, and I conclude generally, as a safe, practical one, (2) on this doubled, as the annual yield when in full bearing all interested I think I may say in this neighborhood, without guessing calculate can be relied on.

It will be understood that a doubled yield does not necessarily involve double expenditure, though as done, something extra must be charged to meet picking, transport, &c:—

At 15 cwt. per Acre.

(East Matale.)

	Per cwt. R.		Expenditure. R.	Nett profit
1 Sheriwardhun ...	... 40	600	100	500
2 Bassein	... 30	450	—	350
3 Southern India ...	... 27	405	—	305
4 Goa and other produce	... 22	330	—	230
5 Ceylon at Galle or Colombo... ...	... 10	150	70	80
6 On Mr. Borron's figures, on estate (I speak under correction) ...	... —	87	47	40

At 30 cwt. per acre.

(Udagama.)

		Expenses.	Nett profit.
(1)	1,200 ...	150 ...	1,050
(2)	900 ...	— ...	750
(3)	810 ...	— ...	660
(4)	660 ...	— ...	510
(5)	300 ...	100 ...	200
(6)	180 ...	70 ...	110

The above would seem to afford a curious illustration of how produce relating principally to the home market is apt to absorb and monopolize public attention. Had arecas been an article of European consumption principally, though with a quarter the demand, the merits of the industry would long since, no doubt, have been dwelt on and discussed in the papers by the yard. Your evening contemporary, I noticed, recently felt constrained to allude to it as a promising "minor" industry; but how, save still in its *minority*, this can be so only on data as at the present, it would be interesting and very important to be shown; and, now that the minds of men seem generally turned to the East, possibly it may inspire more serious notice in the press. The Editor of the *Examiner*, in reviewing Mr. Borron's letter, I see, agrees in a closer system of planting, and also, evidently from an independent source, reverts to the superior merits of the Shirwardun and Mysore nuts. Though hardly likely to be able to throw much light on statistics, there is much useful information many natives no doubt can give, and I trust now will come forward with—for or against.

As far as I can make of it at present, as I said before, it seems to me to be a more easy and certain, as well as more profitable and less costly—and, when the interminable supplying necessary for the latter is considered, not less early—an industry than cocoa; that, but as regards quicker returns, it in every respect claims place beside tea, and is capable even as "wheeler" if the traces of the latter are cut by over-production or otherwise.

The great need now is to show the reverse side of the picture, if it exists. And, if this is to be done, it seems to me it must be on the following queries:—(1) Is, anyhow, 15 cwt. an acre really a fair estimate of yield? (2) Granted the prices quoted above as correct, are they abnormal? or, if they are not, would an extensive increase of cultivation as now going on here for tea render them so? Under this heading I am endeavoring to obtain full information, which, if successful, shall be given.—R.

IMPROVED SIROCCO TEA DRIERS

are thus noticed in the *Indian Planters' Gazette:*—

The season for the purchase of tea machinery having returned, the different makers have come forward with the results of their labours towards improvement, with which they have been occupied during the, to them, dull season. Mr. S. C. Davidson has been hard at work on his "Siroccos," and has completely revolutionised the whole character of his Driers; yet so ably has this been done that possessors of his old "Siroccos" of the "No. 1" and "No. 2 B" class can convert their Driers to the new system at the trifling cost of £23 for the new material, and a few hours' work, and thus increase the working-capacity of their Driers by two-thirds. A few extra trays are also required at the extra cost of 22 shillings each. With characteristic enterprise Mr. Davidson has brought over one of his old converted "Siroccos" and two of the new types, and is exhibiting them in Gracechurch Street, where I have had an opportunity of inspecting them. I hear that he is about to send you out an illustration of a "Sirocco" set up on the new system, and so I need not enter too particularly here into description, as the illustration, which I have already seen, conveys a far better idea than could be given in writing. The converting process I can, however, assure your readers is a very easy matter to effect; and with the aid of a few coolies, most managers could easily perform the whole operation, after the new parts have been put together on the ground, in half a day without skilled assistance. A new working table or *machan* is required, as shown in the illustration, and the attendants stand on the two tables, one at each end of the long drying chamber. There are two rows of four trays each, one row above the other. The green leaf is placed upon the top tray immediately above the stove. As the tray with the *pucca* dried tea is removed from the *lower* tray above the stove, the attendant at the other end places the *upper* tray nearest to him on the lower row, having pushed the other three *lower* trays forward at one shove to make room for it. Then the feeder at the stove-end pushes the top three trays forward, and makes room for his fresh tray of *cutcha* leaf. Once all eight trays are in position, there is little interval between putting on the top fresh tray and removing the lower finished tray, so the attendants are kept well occupied. The heat from the stove thus strikes up hot against the *cutcha* leaf on the top tray, as it has only the thin layer of dried tea to pass through, and it will be found that an equivalent in this arrangement of the stages of wet and dry tea is maintained in each couple of top and bottom trays. Thus when half-dried at the further end from the stove, the two about half-dried trays are one above the other. And as the heat from the second to the fourth tray rises, as tested by experiment, almost exactly equally all along the chamber, this ensures great evenness in the drying. A little excess of temperature is noticeable rising through the trays immediately above the stove, and this has the advantage of both immediately checking the fermentation of the *cutcha* leaf on the *top* tray, and briskly finishing off the *pucca* tea on the *lower* tray. No waste heat now is lost up the chimney, and it is all dispersed from the upper four trays, hence it can be utilised for withering in *machans* overhead. The lowest *machans*, however, should not be less than six feet above the "Sirocco," as it is found, that if too close down, it baffles the draught from the trays and retards the drying, by keeping the steam down over the trays. The drying-chamber takes the old trays with the addition of a slight *baton* screwed on to each. The old drying-chamber-front with the holes for the drawers is done away with, the iron-sheet of which it consists, being replaced by a whole-sheet provided for the purpose. A few bricks are required to support the chimney in its new position. The new "Siroccos" Nos. 3, 4 and 5 having been constructed throughout on the new principle, and having certain substantial improvements in the stove, will show a great increase in outturn, even over the converted ones. In any case in offering a Drier (No. 5) which he maintains will turn out 15 to 17 maunds of dried tea in ten hours at so low a price as £95 packed and f. o. b. at Liverpool or Glasgow, Mr. Davidson has made a very great stride in the advantages now offered to tea planters. His enterprise is reaping good fruit, as he has already sold 50 "Siroccos" of the new types within the past fortnight, which speaks well of the opinion held concerning them by the number of planters who have eagerly "rushed" to look at this the last thing in Driers.—*Planters' Gazette.*

COCOAS, RAW AND MANUFACTURED.

BY E. J. EASTES AND E. TERRY.

Cocoa is obtained from the seeds of *Theobroma Cacao.* This plant is so well known that there is no need to enter on a long description of it. It is a native of Tropical America, where it is extensively cultivated. It has also been introduced into the East Indies and parts of Africa and Australia, but all our important supplies are drawn from America and the West Indies.

Seeds from different cocoa districts vary considerably in appearance, flavour and composition.

As soon as gathered, the seeds, with a small portion of the moist pulp of the fruit adhering, are submitted to a kind of fermentation called the "sweating" process for a few days. This is accomplished in one of two ways, either by piling them while still moist in heaps and allowing them to dry slowly in the sun, being turned over at intervals; or by burying in the ground for a length of time and afterwards drying in the sun or by artificial heat. This fermentation is considered to be analogous to the malting of barley, germination being started and then arrested. It is during this process that the alkaloid theobromine is said to be formed. This sweating operation requires to be conducted with great care, as on it the flavour of the seeds depends. When quite dry the raw cocoa is fit for exportation.

About 13 or 14 per cent of the raw seeds is husk, which is rejected in the process of manufacture of all but the very commonest kinds. The average composition of the raw seed, *minus* husk, is as follows, being the highest and lowest of a long series of published analyses:—

Fat	43–50 in 100 parts.
Albuminoids	13–20 ,,
Starch, Gum, etc.	15–22 ,,
Theobromine	1-2 ,,
Mineral matter	3–4 ,,
Moisture and other constituents	6–12 ,,

We have analysed eight samples of raw commercial cocoas with the following results. The figures are calculated from the seed only, after removal of the husk:—

	Moisture.	Fat.	Ash.	H_3PO_4.	Theobromine
Caraccas ...	4·75	53·65	2·76	1·36	1·08
Carupano ...	5·01	47·38	3·69	1·39	·87
Grenada ...	5·59	47·12	2·81	·91	1·42
Guayaquil ...	3·68	52·97	3·28	·85	1·74
Para ...	4·39	57·07	3·09	1·3	1·
Surinam ...	2·55	53·70	2·44	·85	1·42
Trinidad (common) ...	5·62	45·71	2·79	·89	1·05
Trinidad (fine, San Antonio)	4·72	53·57	2·70	1·15	1·94

The averages of the above figures give percentages differing slightly from those usually stated. We find the fat rather more, and the phosphates rather less.

The raw seeds, before manufacturing, are roasted for about an hour at a moderate heat, which develops the flavour, and allows them to be easily separated from the shell.

Cocoa nibs are merely the roasted seeds freed from their husks, and slightly crushed. This is the purest form in which cocoa can be obtained. But the nibs will not make an elegant, nor an easily digestible beverage, nor are they economical, the method of preparation being merely to boil or simmer with water for some time. The theobromine with some colouring and flavouring matter is dissolved out to a certain extent, the fat rises to the top as an oily layer, but the valuable albuminoids are almost entirely lost. There is the further disadvantage of their requiring a long time to cook.

Two methods have been proposed to obviate these disadvantages, and each has its warm advocates among manufacturers and consumers, the main object being to enable the whole of the valuable food material of the seed to be taken into the system in an easily assimilable form.

The older method is to crush the nut in heated mills, and rub it into a smooth paste, which is mixed with sugar and starch. The addition of these substances causes the formation of an emulsion when boiling water is added. This method gives a pleasant drink, easily made, very nourishing, containing the whole substance of the seed. But it has one disadvantage, namely, the great ease with which the cocoa can be adulterated. In the cheaper varieties the starch and sugar are present in large excess, while the amount of cocoa present is very minute in quantity. Mineral colouring matter is added for the purpose of improving the appearance.

We analysed two well-known cocoas, selling at sixteen and fourteen pence the pound, with results as follows :—

Moisture.	Ash.	H_3PO_4.	Albuminoids.	Fat.	Starch, Sugar, Gum etc.
I. 4·53	1·82	·27	6·33	7·35	79·97
II. 5·05	1·74	·47	9·64	14·82	68·95

These may be considered as fair specimens of the best of their class. Two other samples selling at 6*d.* and 8*d.* per pound furnished about 3 per cent of ash, mainly oxide of iron and silica, and gave traces only of phosphate. The beverage prepared from them was the reverse of delectable.

The other variety of so-called soluble cocoa (neither are soluble in the chemical sense of the word) is manufactured by abstracting a portion of the fat. This is done by grinding the nibs, and then pressing them in bags at a sufficiently high temperature to cause the fat to melt, and the greater portion of it is thus removed. That, which remains in the bags can be finely powdered, and in that state is readily diffusible through hot water. Samples I., II. III. are sold respectively at 2*s.* 8*d.*, 4*s.* 6*d.* and 3*s.* 6*d.* the pound (about).

Moisture.	Ash.	H_3PO_4.	Albuminoids.	Fat.	Starch, Sugar, Gum etc.
I. 5·72	4·66	2·3	19·43	21·49	48·7
II. 3·16	5·99	1·84	23·23	33·21	34·41
III. 3·85	7·76	2·10	12·72	27·88	47·79

No. III., though enjoying a very high reputation, gives analytical results which seem to point to adulteration.—*Pharmaceutical Journal.*

RHEA FIBRE.

Several applications for information regarding Rhea have been received by the Agricultural and Horticultural Society of India, owing no doubt to the attention excited by the late Fibre-machine trials held under the auspices of the Bengal Government. Such information as has been at the disposal of the Society has been afforded to applicants. The following report on samples sent by Messrs. Begg, Dunlop & Co., prepared at Bareilly was furnished by the President:—"I have carefully examined the following samples of RheaFibre under a Coddington Lens, and have pleasure in reporting as follows:—No. 1.—Fair to moderately long, soft staple, greyish white color, produced by the application of chemicals to bleach it, an excess of which has rendered most of the Fibre exceedingly weak and towy in appearance, so much so, that much of it would be reduced to tow only in the combing process, to which it must be subjected in manufacture. No. 2.—Staple harsh, short, irregular, uneven, tender to somewhat weak in strength, little towy, and of but poor color; some sticky with original bark adhering, and not freed from gumminess. With care and greater experience, which can only be gained by repeated trial, these samples indicate that much better results may be achieved. In this country no commerical value can be attached to them, but if further preparations were submitted, freed from the objectionable features I have pointed out, I would recommend that large samples be sent to London for a full report and valuation." The Society remarks that "hitherto on this side of India all the Rhea grown has been propagated by cuttings and division of roots as the seed has never proved fertile." The following communication is therefore of great interest, as should Rhea be largely cultivated, the slow process of propagation by cuttings would prove expensive, and a great obstacle to the industry cutting a fair start, as the stock of plants available for the purpose is limited.—"The small packet of Rhea Seed I left with you on the 25th instant was obtained from plants grown in my garden and they again were propagated from imported seed. As it will be interesting to the public to know that acclimatized seed germinates out here, you will be good enough to announce the fact in an early issue of the Society's Journal."—*Madras Mail.*

LIME AND LEMONS.

Sir,—In reply to your correspondent "Citrons" in your issue of the 30th ultimo, allow me to state that under the head of Limes (*Citrus Limetta*) the lemon (*Citrus Limonium*) should be included; its fruits are chiefly valuable on account of their juice, which is largely used as an anti-scorbutic, and if shipped to England will find a ready market. The juice is obtained freed of its rind and seeds by pressure in this country; in the absence of machinery, the common lime squeezer answers the purpose very well. The juice, when extracted, should be allowed to stand for a few days in a cool place, and then filtered and decanted; as it consists chiefly of citric acid dissolved in water with mucilage and extractive it is apt to undergo decomposition, but with care may be preserved for a considerable period by corking it up in full bottles, or by pouring a layer of sweet or olive oil above it. Some subject it to a slight ebullition. I have here preserved the lime juice for over two years in well-corked and dammered bottles. Lime juice contains 6 per cent citric acid, to which it owes its sourness, and from which it might be readily separated by a simple chemical process. This acid is used in medicine as a refrigerent and anti-scorbutic, and as a substitute for the lime juice itself. Lime juice, in its fresh state, is much esteemed for flavouring punch, sherbet, and other beverages. The rind or lime peel is of a light yellow color, but becomes brown when dried; it is used in medicine and confectionery. It also contains a volatile oil which may be separated by distillation; the oil is used in medicine, and is much esteemed for flavouring purposes as well as a scent. The fruit of the lime is highly esteemed by natives; they present it to their superiors as well as friends on festive and ceremonial occasions. If the lime be quartered half through and salted and dried, it may be preserved for long periods, and can be readily converted into pickle by the addition of vinegar. The salted lime finds a ready sale at most villages, or it may be exported; it may also be pickled in its own juice, and sent for sale or exported to England. The sweet lime is chiefly used as a refrigerent, and during the hot weather the natives drink the juice; they also are partial to this fruit, which to the European is tasteless and insipid. The citron or *Citrus medica*, the rind of which forms a delicate sweetmeat by being candied, is also made into marmalade or chutney—the natives are partial to this fruit, which they pickle chiefly in oil. The Shaddock or Pumplemose, known scientifically as *Citrus decumana*, is believed to be the "Forbidden Fruit," and is chiefly valued as a fruit. It attains a large size, the rind abounds with a volatile oil, which might be turned to account on these Hills, whilst the tree fruits largely, the branches breaking down with the load, but they are worthless as a fruit; even the best varieties are bitter and acrid, and totally unfit for use, and I am glad to transfer them to the manure pit to which they become a valuable addition by the citric acid and volatile oil they contain.—JOHN SHORTT.—*Madras Mail.*

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's London Price Current, May 7th, 1885.)

FROM MALABAR COAST, COCHIN, CEYLON, MADRAS, &c.	QUALITY.	QUOTATIONS.
